Chapter 1

Introduction

This thesis presents a method for communication analysis out of the captured assembly level execution traces. The dual_trace being discussed throughout this thesis consists of two assembly level execution traces of two running programs. This work aims to help reverse engineers to understand the behavior of the interacting programs in the assembly level. There are many reasons for investigating programs in assembly level. Lacking of source code and trying to understand the memory usage are one among those reasons.

Many network application vulnerabilities occur while one program is running isolatedly, but while it is interacting with other systems. These vulnerabilities can be difficult to analyze and detect. Dual_trace analysis is an approach that helps the security engineers to detect the vulnerabilities in the interactive programs. The two traces in dual_trace contain information including CPU instructions, register and memory changes, system calls, modules and threads of the running application. Communication information of the interacting programs can be retrieved from the captured information in the dual_trace.

In this work, I first modeled the communication between two programs. This model defines the communication objects under investigation and identified in the dual_trace. In simplification, a communication is completed between two programs each of which corresponds to a sequence of events. An event can be one of four different event types (channel open, data send, data receive and channel close). However the actual events are various according to the communication method and the user concern. Then, I modeled the dual_trace, excluding the irrelevant information while abstracting the information related to the communications. Furthermore, I investigated the implementation of the communication methods in Windows. The result of the investigation provides some guidelines and examples of how to draw the concerned event list as described in the communication model which is the prerequisite of the communication identifications. By matching

the elements in the communication model and the dual_trace model, I developed the communication identification algorithms. To provide more concrete idea, I implemented the communication identification features in Atlantis[5], an assembly execution trace analysis environment.

Finally, I tested the models and the algorithms by two experiments. The experiment result shows that 1) the existing dual_trace contain sufficient information for communication analysis based on the designed models. In addition. 2) the developed algorithm can effectively identify the communications from the dual_trace. This work is a collaborative work with our research partner DRDC. In the experiment tests, DRDC captured the dual_traces with its home-make pin tool of the programs running in DRDC's environment. I conducted the analysis of the provided dual_traces as long as the dynamic libraries of the running environment locally.

Chapter 2

Background

This section introduces several background knowledge or information that related to this work. First I describe what is software security and how important it is as well as our existing approach to assist detection of software vulnerabilities by assembly level trace analysis. Second, I discuss how software interaction affect the behavior of the software and the common communications among programs. Third, I introduce some tools for assembly level program debugging and analysis. One of those is Atlantis, the existing assembly level execution trace analysis environment, on which the implementation of this work based.

2.1 Software Security and Vulnerability Detection

The internet grows incredibly fast in the past few year. More and more computers are connected to it in order to get service or provide service. The internet as a powerful platform for people to share resource, meanwhile, introduces the risk to computers in the way that it enable the exploit of the vulnerabilities of the software running on it. Accordingly, the emphasize placed on computer security particularly in the field of software vulnerabilities detection increases dramatically. It's important for software developers to build secure applications. Unfortunetely, this is usually very expensive and time consuming and somehow impossible. On the other hand, finding issues in the built applications is more important and practical. However this is a complex process and require deep technical understanding in the perspective of reverse engineering.[3].

A common approach to detect existing vulnerabilities is fuzzing testing, which record the execution trace while supplying the program with input data up to the crash and perform the analysis of the trace to find the root cause of the crash and decide if that is a vulnerability[2]. Execution trace can be captured in different levels, for example object level and function level. But my re-

search only focus on those that captured in instruction and memory reference level. There are two main reasons for analysis system-level traces. First, it is for analysis of the software provided by vendor whose source code are not available. The second one is that low level trace are more accurately reflect the instructions that are executed by multicore hardware[11].

2.2 Program Communications

Applications nowadays do not always work isolately, many software appear as reticula collaborating systems connecting different modules in the network[?] which make the discovery of vulnerabilities even harder. The communication and interaction between modules affect the behaviour of the software. Without regarding to the synergy information, analysis of the isolated execution trace on a single computer is usually futile. There are several methods for communication between programs. These methods can be categorized based on different perspective. One of these categorization is Internet versus Inter-process while the other one is reliable versus unreliable. In this work, communication methods belong to all these four categories has been covered. However, I only discuss the message based communication methods while leave the control based communication, like remote function call for the future.

2.3 Program Execution Tracing in Assembly Level

There are many tools that can trace a running program in assembly instruction level. IDA pro [4] is a widely used tool in reverse engineering which can capture and analysis system level execution trace. Giving open plugin APIs, IDA pro allows plugin such as Codemap [7] to provide more sufficient features for "run-trace" visualization. PIN[6] as a tool for instrumentation of programs, provides a rich API which allows users to implement their own tool for instruction trace and memory reference trace. Other tools like Dynamic [1] and OllyDbg[12] also provide the debugging and tracing functionality in assembly level.

Atlantis is a trace analysis environment develop in Chisel. It can support analysis for multi-gigabyte assembly traces. There are several features distinct it from all other existing tools and make it particularly successful in large scale trace analysis. These features are 1) reconstruction and navigation the memory state of a program at any point in a trace; b) reconstruction and navigation of system functions and processes; and c) a powerful search facility to query and navigate traces. The work of this thesis is not an extension of Atlantis. But it takes advantages of Atlantis by reusing its existing functionality to assist the dual_trace analysis.

Chapter 3

Modeling

In this chapter, I modeled the communication of two running programs. The dual-trace captured from two interacting programs are also modeled in the perspective of communication analysis. The modeling are based on the investigation of some common used communication methods. The communication methods are divided into two categories based on their data transmission properties. This modeling are the foundation to decide how communications being identified from the dual-trace and how to present them to the user. The terminology of using in this chapter can be found in A.

3.1 Communication Categorization and Communication Methods

The goal of this work is to identify the communications from the dual-trace. We need to understand the properties of the communications to identify them. In general, there are two types of communication: reliable and unreliable in the terms of their reliability of data transmission. The reason to divide the communication methods into these two categories is that the data transmission properties of the communications fall in different categories affect the mechanism of the data verification in the identification algorithm. In the following two subsections, I summarize the characteristics of these two communication categories. The communication methods list in Table3.2 will be discussed further to provide more concrete comprehension.

Table 3.1: Communication Methods Discussed in This Work

Reliable Communication	Unreliable Communication
Named Pipes	Message Queue
TCP	UDP

3.1.1 Reliable Communication

A reliable communication guarantees the data being sent by one endpoint of the channel always received losslessly and in order to the other endpoint. For some communication methods, a channel can be closed without waiting the completion of all data transmission. With this property, the concatenated data in the receive stream of one endpoint should be the sub string of the concatenated data in the send stream of the other endpoint. Therefore, the send and receive data verification should be in send and receive stream level by comparing the concatenated received data of one endpoint to the concatenated sent data of another.

3.1.2 Unreliable Communication

An unreliable communication does not guarantee the data being sent always arrive the receiver. Moreover, the data packets can arrive to the receiver in any order. However, the bright side of unreliable communication is that the packets being sent are always arrived as the origin packet, no data re-segmentation would happen. Accordingly, the send and receive data verification should be done by matching the data packets in a receive event to a send event on the other side.

3.1.3 Communication Methods

In this section, I describe the mechanism and the basic data transfer characteristics of each communication method in Table 3.2 briefly. Moreover, data transfer scenarios are represented correspondingly in diagrams for each communication method.

Named Pipe

A named pipe provides FIFO communication mechanism for inter-process communication. It can be one-way or duplex pipe which allows two programs send and receive message through the named pipe. [8]

The basic data transfer characteristics of Named Pipe are:

- Bytes received in order
- Bytes sent as a whole trunk can be received in segments
- No data duplication
- Only the last trunk can be lost

Based on these characteristics, the data transfer scenarios of Named pipe can be summarized in Figure 3.1.

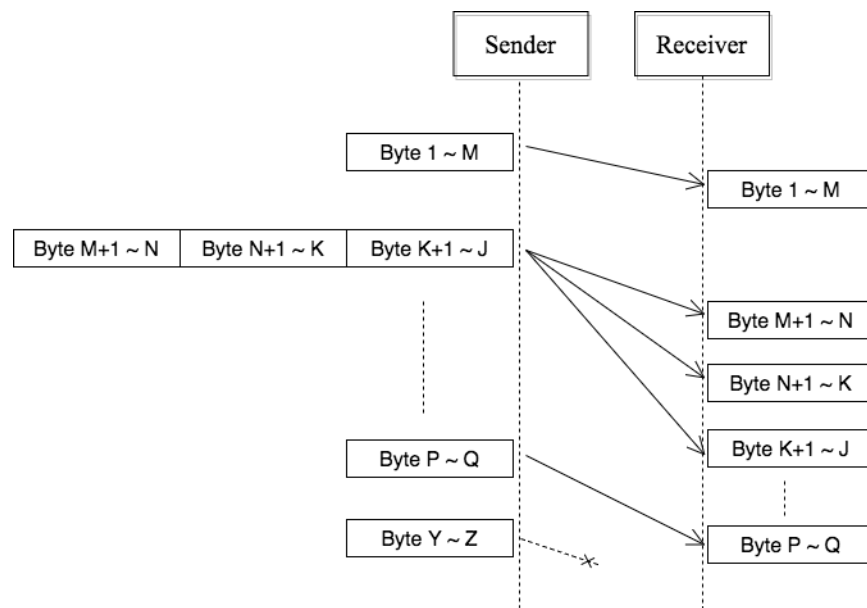

Figure 3.1: Data Transfer Scenarios for Named Pipe

Message Queue

Message Queuing (MSMQ) is a communication method to allow applications which are running at different times across heterogeneous networks and systems that may be temporarily offline can still communicate with each other. Messages are sent to and read from queues by applications. Multiple sending applications can send messages to and multiple receiving applications can read messages from one queue.[10] In this work, only one sending application versus one receiving application case is considered. Multiple senders to multiple receivers scenario can be divided into multiple sender and receiver situation. Both applications of a communication can send to and receive from the channel.

The basic data transfer characteristics of Message Queue are:

- Bytes sent in packet and received in packet, no bytes re-segmented
- Packets can lost
- Packets received in order
- No data duplication

Based on these characteristics, the data transfer scenarios of Message Queue can be summarized in Figure3.2.

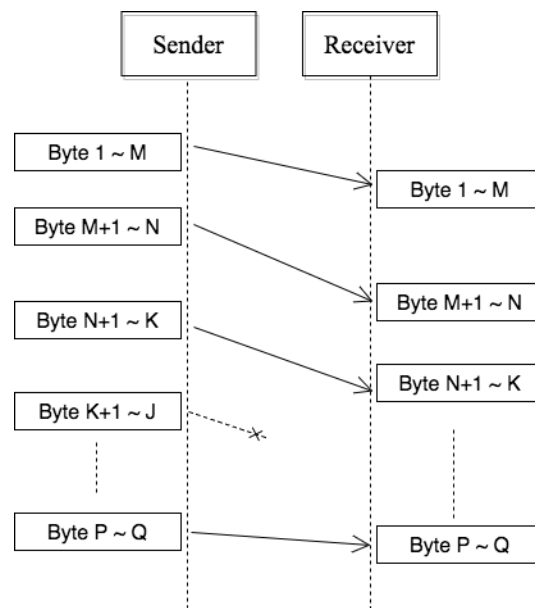

Figure 3.2: Data Transfer Scenarios for Message Queue

TCP

TCP is the most fundamental reliable transport method in computer networking. TCP provides reliable, ordered, and error-checked delivery of a stream of octets between applications running on hosts in an IP network. The TCP header contains the sequence number of the sending octets and the acknowledge sequence this endpoint is expecting from the other endpoint(if ACK is set). The re-transmission mechanism is based on the ACK.

The basic data transfer characteristics of TCP are:

- Bytes received in order
- No data lost (lost data will be re-transmitted)

- No data duplication
- Sender window size is different from receiver's window size, so packets can be re-segmented

Based on these characteristics, the data transfer scenarios of TCP can be summarized in Figure3.3.

Figure 3.3: Data Transfer Scenarios for TCP

UDP

UDP is a widely used unreliable transmission method in computer networking. It is a simple protocol mechanism, which has no guarantee of delivery, ordering, or duplicate protection. This transmission method is suitable for many real time systems.

The basic data transfer characteristics of UDP are:

- Bytes sent in packet and received in packet, no re-segmentation
- Packets can lost
- Packets can be duplicated
- Packets can arrive receiver out of order

Based on these characteristics, the data transfer scenarios of UDP can be summarized in Figure3.4.

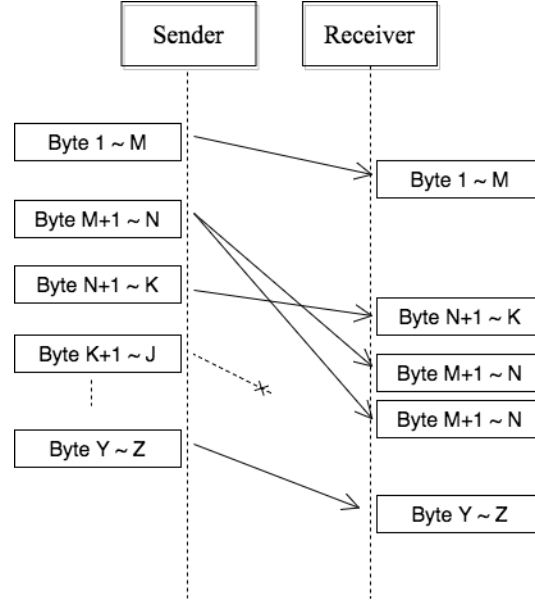

Figure 3.4: Data Transfer Scenarios for UDP

3.2 Communication Model

The communication of two programs is defined in this section. The communication in this work is data transfer activities between two running programs through a specific channel. Some collaborative activities between the programs such as remote procedure call is out of the scope of this research. Communication among multiple programs (more than two) is not discussed in this work. The channel can be reopened again to start new communications after being closed. However, the reopened channel will be treated as a new communication. The way that I define the communication is leading to the communication identification in the dual-trace. So the definition is not about how the communication works but what it looks like. There are many communication methods in the real world and they are compatible to this communication definition.

3.2.1 Communication Definition

In the context of a dual_trace, a communication is a sequence of data transmitted between two endpoints through a communication channel. The endpoints connect to each other using the identifier of this channel. We therefore defined a communication c as a tripled:

$$c = \langle ch, e0, e1 \rangle$$

where $e0$ and $e1$ are endpoints and where ch is the communication channel used (e.g. a named

pipe located at /tmp/pipe).

For the purpose of modelling the trace, the endpoints e_0 and e_1 are defined in terms of three properties: the handle created within a process for the endpoint for subsequent operations (such as data send and receive), the data stream received and the data stream sent. Therefore, we define an endpoint e as a triplet:

$$e = \langle handle, d_r, d_s \rangle$$

From the point of view of a trace, a data stream is a sequence of events that send or receive a package. Each package is composed contains data that is being sent or received (its payload). Hence, we can define a data stream d as a sequence of n packages:

$$d = (pk_1, pk_2, \dots, pk_n)$$

Note that this is the sequence of packages as seen from the end-point and might be different than the sequence of packages seen in the other end point, specially where there is package reordering or loss.

Each package has several attributes:

- *Relative time(it was sent or received)*: In a trace, we do not have absolute time for an event. However, we know when an event (i.e. sending or receiving a package) has happened with respect to another event. we will use the notation

$$time(pkg)$$

to denote this relative time. Hence, if

$$i < j$$

, then

$$time(pk_i) < time(pk_j)$$

- *Payload*: Each package has a payload (the data being sent). This payload can be modeled as a string contained in the package. we will use the notation

$$pl(pkg)$$

to denote this payload.

3.2.2 Communication Properties

The properties of the communications can be described based on the definition of the communication.

Properties of reliable communication:

A reliable communication guarantees that the data sent and received between a package happens without loss and in the same order.

For a given data stream, I will define the data in this stream as the concatenation of all the payloads of all the packages in this stream, in the same order, and denote it as $data(d)$.

Given $d = \langle pk_1, pk_2, \dots, pk_n \rangle$, $data(d) = pl(pk_1) \cdot pl(pk_2) \cdot \dots \cdot pl(pk_n)$

- *Content Preservation:* for a communication:

$c = \langle ch, \langle h0, dr0, ds0 \rangle, \langle h1, dr1, ds1 \rangle \rangle$

the received data should always be a prefix (potentially equal) of the data sent:

$data(dr0)$ is a prefix of $data(ds1)$ and

$data(dr1)$ is a prefix of $data(ds0)$

- *Timing Preservation:* at any given point in time, the data received by an endpoint should be a prefix of the data that has been sent from the other:

for a sent data stream of size m , $ds = \langle pks_1, pks_2, \dots, pks_m \rangle$ that is received in data stream of size n , $dr = \langle pkr_1, pkr_2, \dots, pkr_n \rangle$

for any $k \in 1..n$, there must exist $j \in 1..m$ such that: pks_j was sent before pkr_k was received:

$time(pks_j) < time(pkr_k)$

and

$data(\langle pkr_1, pkr_2, \dots, pkr_k \rangle)$ is a prefix of $data(\langle pks_1, pks_2, \dots, pks_j \rangle)$

In other words, at any given time, the recipient can only receive at most the data has been sent.

Properties of unreliable communication:

In unreliable communication sender and receiver are not concerned with the concatenation of packages. Instead, they treat each package independent of each other.

- *Content Preservation:* a package that is received should have been sent:

for a sent data stream of size m , $ds = \langle pks_1, pks_2, \dots, pks_m \rangle$ that is received in data stream of size n , $dr = \langle pkr_1, pkr_2, \dots, pkr_n \rangle$

for any $pk_{r_j} \in dr$ there must exist $pk_{s_i} \in ds$

We will say that the pk_{r_j} is the matched package of pk_{s_i} , and vice-versa, pk_{s_i} is the matched package of pk_{r_j} , hence

$$match(pk_{r_j}) = pk_{s_i} \text{ and}$$

$$match(pk_{s_i}) = pk_{r_j}$$

- *Timing Preservation:* at any given point in time, packages can only be received if they have been sent

for a sent data stream of size m , $ds = \langle pk_{s_1}, pk_{s_2}, \dots, pk_{s_m} \rangle$ that is received in data stream of size n , $dr = \langle pk_{r_1}, pk_{r_2}, \dots, pk_{r_n} \rangle$

$$\text{for any } k \in 1..n, time(match(pk_{r_j})) < time(pk_{r_j})$$

In other words, the match of the received package must have been sent before it is received.

In the following two examples, $h0$ and $h1$ are the handles of the two endpoints $e0$ and $e1$ of the communications. $ds0$, $dr0$ and $ds1$, $dr1$ data streams of the endpoints $e0$ and $e1$. The string payloads are the strings represented in blue and red in the figures.

Figure3.5 is an example of the reliable communication.

The payloads of the packages are:

$$pl(pk_{s0_1}) = \text{"ab"}, pl(pk_{s0_2}) = \text{"cde"}, pl(pk_{s0_3}) = \text{"fgh"};$$

$$pl(pk_{r1_1}) = \text{"abc"}, pl(pk_{r1_2}) = \text{"def"}, pl(pk_{r1_3}) = \text{"gh"}.$$

and

$$pl(pk_{s1_1}) = \text{"mno"}, pl(pk_{s1_2}) = \text{"pqr"}, pl(pk_{s1_3}) = \text{"stu"};$$

$$pl(pk_{r0_1}) = \text{"mnop"}, pl(pk_{r0_2}) = \text{"qrst"}.$$

on the other direction. Their properties:

$$pl(pk_{s0_1}) \cdot pl(pk_{s0_2}) \cdot pl(pk_{s0_3}) = pl(pk_{r1_1}) \cdot pl(pk_{r1_2}) \cdot pl(pk_{r1_3}) = \text{"abcdefgh"} \text{ and}$$

$$pl(pk_{s1_1}) \cdot pl(pk_{s1_2}) \cdot pl(pk_{s1_3}) = pl(pk_{r0_1}) \cdot pl(pk_{r0_2}) = \text{"mnopqrst"}.$$

satisfy the content preservation.

The relative time relationship of the packages are:

$$time(pk_{s0_1}) < time(pk_{s0_2}) < time(pk_{r1_1}) < time(pk_{s0_3}) < time(pk_{r1_2}) < time(pk_{r1_3});$$

$$time(pk_{s1_1}) < time(pk_{s1_2}) < time(pk_{r0_1}) < time(pk_{s1_3}) < time(pk_{r0_2}).$$

The fact that

$$pl(pk_{r0_1}) = \text{"mnop"} \text{ is the prefix of } pl(pk_{s1_1}) \cdot pl(pk_{s1_2}) = \text{"mnopqr"},$$

$$pl(pk_{r0_1}) \cdot pl(pk_{r0_2}) = \text{"mnopqrst"} \text{ is the prefix of (is this case identical to) } pl(pk_{s1_1}) \cdot$$

$$pl(pk_{s1_2}) \cdot pl(pk_{s1_3}) = \text{"mnopqrst"},$$

$pl(pkr1_1) = "abc"$ is the prefix of $pl(pks0_1 \cdot pl(pks0_2) = "abcde"$,
 $pl(pkr1_1) \cdot pl(pkr1_2) = "abcdef"$ and $pl(pkr1_1) \cdot pl(pkr1_2) \cdot pl(pkr1_3) = "abcdefgh"$ are the
 prefix of $pl(pks0_1) \cdot pl(pks0_2) \cdot pl(pks0_3) = "abcdefgh"$
 satisfy the timing preservation.

Figure 3.5: Example of Reliable Communication

Figure 3.6 is an example of the unreliable communication. In this example:

- $pkr1_1 = pks0_2 = "cde", time(pkr1_1) > time(pks0_2);$
- $pkr1_2 = pks0_3 = "fi", time(pkr1_2) > time(pks0_3);$
- $pkr0_1 = pks1_1 = "gh", time(pkr0_1) > time(pks1_1);$
- $pkr0_2 = pks1_2 = "ijklm", time(pkr0_2) > time(pks1_2);$
- $pkr0_3 = pks1_3 = "n", time(pkr0_3) > time(pks1_3).$

All of these satisfy the content preservation and timing preservation of the unreliable communication.

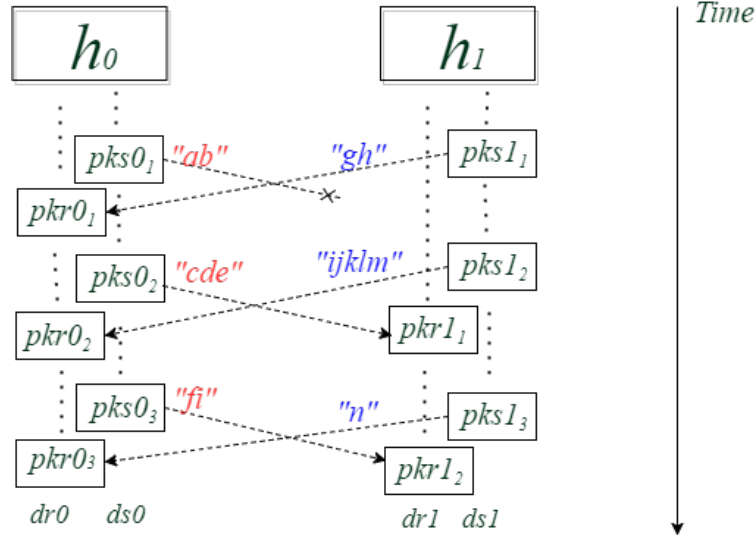

Figure 3.6: Example of Unreliable Communication

3.3 Dual-Trace Model

In this section, I model the execution trace in the dual-trace. The modeling aims at identify the communications from the information summarized in the model.

Before the modeling, I describe the facts of the dual-trace being analyzed. The traces in a dual-trace are in assembly level. One dual-trace contains two execution traces. There is no timing information of these two traces which means we don't know the time-stamps of the events of these two traces and can not match the events from both sides by time sequence. However the captured instructions in the trace are ordered in execution sequence. The execution traces contain all executed instructions as well as the corresponding changed memory by each instruction. Additionally, system calls are also captured by instruction id, which means if .dll or .exe files are provided, the system function calls can be identified with function names. Memory states can be reconstructed from the recorded memory changes to get the data information of the communication.

In this model, a *dual_trace* consist of two execution traces which are $\{trace_x : x = 0, 1\}$. An execution *trace* is defined as a sequence $(line_k, 0 \leq k \leq K)$. $line_k$ in a *trace* is a 3_tuple $\langle ins, mem, inf \rangle$ where *ins* is the assembly instruction, *mem* is memory changed by this instruction and *inf* is function call information. This information includes an indicator of function call and return and the function's name if applicable. A function *eventfilter*() is defined to generate the event level trace $event_trace_x$ from the original $trace_x$. So that $event_trace_x = event_filter(trace_x, funcset)$, where $funcset = \{func_l, 0 \leq l \leq L\}$ is a set of the concerned

events' function information. Each concerned event's function information can be described a tuple $\langle funN, type, pars \rangle$ where $funN$ is the function name, $type$ can only be one of these four event types: channel open, channel close, data send and data receive, $pars$ is the parameter information list. The output of this function $event_trace_x$ is a sequence of events $(event_{x,m}, 0 \leq m \leq M_x)$. Only the concerned events in the $funcset$ are filtered in this sequence, all other information in the original trace are ignored. Each event in the trace corresponds to a system function call and is defined as a 6-tuple $\langle funN, startline, endline, inputs, outputs, type \rangle$. In this tuple $funN$ is the name of the called function, $startline$ is the line number where the function was being called, $endline$ is the line number where the function returned and $type$ is the event type. The events in the $event_trace_x$ are interleaving events among multiple handles. Function $streamfilter()$ is defined to generate the stream level trace $stream_trace_x$ from the $event_trace_x$ so that $stream_trace_x = streamfilter(event_trace_x)$. The output $stream_trace_x$ is a set of stream $\{stream_{x,n}, 0 \leq n \leq N_x\}$ in which each stream corresponds to a handle, a channel id and consist of 4 sub streams. So $stream_{x,n}$ is a 6-tuple $\langle handle, channelid, open_stream, send_stream, receive_stream, close_stream \rangle$. Each of these sub streams consist of a sequence of *event* of a certain handle of the corresponding event types.

3.4 Element Matching Communication Model and Dual-Trace Model

The identification the communication from dual-trace can be simply abstracted as finding the elements of the communication model in the dual-trace model. The element matching can be summarized in Table 3.4. By known this matching, algorithms can be developed to identify the communications in the dual-trace model. The developed algorithm will be discussed in next chapter.

Table 3.2: Element Matching of Communication and Trace Models

Communication Model Element	Trace Model Element
c	matching <i>channelid</i> in two <i>stream</i> respectively of $trace_0$ and $trace_1$
ep_x	a <i>stream</i> in $trace_x$
h_x	<i>handle</i> of a <i>stream</i> in $trace_x$
ds_x	a <i>send_stream</i> of a <i>stream</i> in $trace_x$
dr_x	a <i>receive_stream</i> of a <i>stream</i> in $trace_x$
$ps_{x,i}$	a packet send event $event_{x,m}$ in $event_trace_x$
$pr_{x,i}$	a packet receive event $event_{x,m}$ in $event_trace_x$
$ss_{x,i}$	the payload can be find in <i>inputs</i> of an send event $event_{x,m}$
$sr_{x,i}$	the payload can be find in <i>outputs</i> of an receive event $event_{x,m}$

Chapter 4

Communication Identification Algorithms

This chapter discusses the algorithms for communication identification from dual-trace. Pseudo code are listed for algorithms. The algorithm is based on the models developed in the models Chapter3.

4.1 Communication Identification Algorithm

The identification of the communications from a dual_trace should be able to identify the concerned communications as well as all the components defined in it. The inputs of this algorithm are the $dual_trace = \{trace_x : x = 0, 1\}$ and the concerned communication method's function set $funcset = \{func_l, 0 \leq l \leq L\}$. The output of this algorithm is all the identified communications of the concerned communication method. This is a very high level algorithm, details of each step in this algorithm will be discussed in the later sections.

Algorithm 1: Communication Identification Algorithm

Input: $dual_trace, funcset$

Output: $cos = \{co_y : 0 \leq y \leq Y\}$

```

1 for  $x \in (0, 1)$  do
2    $event\_trace_x = eventfilter(trace_x, funcset);$ 
3    $stream\_trace_x = streamfilter(event\_trace_x);$ 
4  $cos = streammatch(stream\_trace_0, stream\_trace_1);$ 
5 return  $cos;$ 

```

4.2 Communication Methods' Implementation in Windows

This section investigate the characteristics and the implementation of the communication methods. The goal of this investigation is to 1) obtain the system function set *funcset* for the concerned events in the communication and summarize the necessary parameters for further communication identification. and 2) understand the channel opening mechanism in order to identify the streams from the *event_trace* and match the streams from two traces.

The implementations of four communication methods in Windows system are investigated. I reviewed the Windows APIs of the communication methods and their example code. For each communication method, a system function list is provided for reference. These lists contain function names, essential parameters. These functions are supported in most Windows operating systems, such as Windows 8, Window 7. The channel opening mechanisms of each method are described in detail and represented in diagrams.

Windows API set is very sophisticated and multiple solutions are provided to fulfil a communication method. It is impossible to enumerate all solutions for each communication method. I only give the most basic usage provided in Windows documentation. Therefore, the provided system function lists for the events should not be considered as the only combination or solution for each communication method. With the understanding of the model, it should be fairly easy to draw out lists for other solutions or other communication methods.

Moreover, the instances of this model only demonstrate Windows C++ APIs. This model may be generalizable to other operating systems with the effort of understanding the APIs of those operating systems.

4.2.1 Windows Calling Convention

The Windows calling convention is important to know in this research. The communication identification relies not only on the system function names but also the key parameter values. In the assembly level execution traces, the parameter values is captured in the memory changes of the instructions. The memory changes are recognized by the register names or the memory address. The calling convention helps us to understand where the parameters are stored so that we can find them in the memory change map in the trace. Calling Convention is different for operating systems and the programming language. The Microsoft* x64 example calling convention is listed in B since we used dual-trace from Microsoft* x64 for case study in this work.

4.2.2 Named Pipes

In Windows, a named pipe is a communication method for the pipe server and one or more pipe clients. The pipe has a name, can be one-way or duplex. Both the server and clients can read or write into the pipe.[9] In this work, I only consider one server versus one client communication. One server to multiple clients scenario can always be divided into multiple server and client communications thanks to the characteristic that each client and server communication has a separate conduit. The server and client are endpoints in the communication. We call the server “server endpoint” while the client “client endpoint”. The server endpoint and client endpoint of a named pipe share the same pipe name, but each endpoint has its own buffers and handles.

There are two modes for data transfer in the named pipe communication method, synchronous and asynchronous. Modes affect the functions used to complete the send and receive operation. I list the related functions for both synchronous mode and asynchronous mode. The create channel functions for both modes are the same but with different input parameter value. The functions for send and receive message are also the same for both cases. However, the operation of the send and receive functions are different for different modes. In addition, an extra function *GetOverlappedResult* is being called to check if the sending or receiving operation finish, the output message will be stored in the overlap structure whose memory address saved in the function’s output parameter Overlap Structure Address. Table4.1 lists the functions of the events for synchronous mode while Table4.2 lists the functions of the events for the asynchronous mode for a Named pipe communication.

Table 4.1: Function List of events for Synchronous Named Pipe

Event	Server Endpoint		Client Endpoint	
	Function	Parameters	Function	Parameters
Channel Open	CreateNamedPipe	RAX: File Handler	CreateFile	RAX: File Handler
		RCX: File Name		RCX: File Name
Channel Open	ConnectNamedPipe	RCX: File Handler		
Send	WriteFile	RCX: File Handle	WriteFile	RCX: File Handle
		RDX: Buffer Address		RDX: Buffer Address
		R9: Message Length		R9: Message Length
Receive	ReadFile	RCX: File Handle	ReadFile	RCX: File Handle
		RDX: Buffer Address		RDX: Buffer Address
		R9: Message Length		R9: Message Length
Channel Close	CloseHandle	RCX: File Handler	CloseHandle	RCX: File Handler
Channel Close	DisconnectNamedPipe	RCX: File Handler	DisconnectNamedPipe	RCX: File Handler

Table 4.2: Function List of events for Asynchronous Named Pipe

Event	Server Endpoint		Client Endpoint	
	Function	Parameters	Function	Parameters
Channel Open	CreateNamedPipe	RAX: File Handler	CreateFile	RAX: File Handle
		RCX: File Name		RCX: File Name
Channel Open	ConnectNamedPipe	RCX: File Handler		
Send	WriteFile	RCX: File Handle	WriteFile	RCX: File Handle
		RDX: Buffer Address		RDX: Buffer Address
		R9: Message Length		R9: Message Length
Receive	ReadFile	RAX: File Handle	ReadFile	RCX: File Handle
		RDX: Buffer Address		RDX: Buffer Address
		R9: Message Length		R9: Message Length
Receive	GetOverlapped-Result	RCX: File Handler	GetOverlapped-Result	RCX: File Handler
		RDX: Overlap Structure address		RDX: Overlap Structure Address
Channel Close	CloseHandle	RCX: File Handler	CloseHandle	RCX: File Handler
Channel Close	DisconnectNamedPipe	RCX: File Handler	DisconnectNamedPipe	RCX: File Handler

A named pipe server is responsible for the creation of the pipe, while clients can connect to the pipe after it was created. The creation and connection of a named pipe returns the handle ID of that pipe. These handler Ids will be used later when data is being sent or received to a specified pipe. Figure4.1 shows the channel set up process for a Named Pipe communication.

Figure 4.1: Channel Open Process for a Named Pipe

4.2.3 Message Queue

Similar to Named Pipe, Message Queue's implementation in Windows also has two modes, synchronous and asynchronous. Moreover, the asynchronous mode further divides into two operations, one with callback function while the other without. With the callback function, the callback function would be called when the send or receive operations finish. Without callback function, the general function *MQGetOverlappedResult* should be called by the endpoints to check if the message sending or receiving operation finish, the output message will be stored in the overlap structure whose memory address saved in the function's output parameter Overlap Structure Address. Table4.3 lists the functions for synchronous mode while Table4.4 and Table4.5 list the functions for the asynchronous mode with and without callback.

Table 4.3: Function List of events for Synchronous MSMQ

Event	Function	Parameters
Channel Open	MQOpenQueue	RAX: Queue Handler
		RCX: Queue Format Name
Send	MQSendMessage	RCX: Queue Handle
		RDX: Message description structure Address
Receive	MQReceiveMessage	RCX: Queue Handle
		R9: Message description structure Address
Channel Close	MQCloseQueue	RCX: Queue Handler

Table 4.4: Function List of events for Asynchronous MSMQ with Callback

Event	Function	Parameters
Channel Open	MQOpenQueue	RAX: Queue Handler
		RCX: Queue Format Name
Send	MQSendMessage	RCX: Queue Handle
		RDX: Message description structure Address
Receive	MQReceiveMessage	RCX: Queue Handle
		R9: Message description structure Address
Receive	CallbackFuncName	Parameters for the callback function.
Channel Close	MQCloseQueue	RCX: Queue Handler

Table 4.5: Function List of events for Asynchronous MSMQ without Callback

Event	Function	Parameters
Channel Open	MQOpenQueue	RAX: Queue Handler
		RCX: Queue Format Name
Send	MQSendMessage	RCX: Queue Handle
		RDX: Message description structure Address
Receive	MQReceiveMessage	RCX: Queue Handle
		R9: Message description structure Address
Receive	MQGetOverlappedResult	RCX: Overlap Structure address
Channel Close	MQCloseQueue	RCX: Queue Handler

In Windows programming, these two methods shared the same set of APIs regardless the input parameter values and operation behaviour are different. In Windows socket solution, one of the two endpoints is the server while the other one is the client. Table 4.6 lists the functions of a UDP or TCP communication.

Table 4.6: Function List of events for TCP and UDP

Event	Server Endpoint		Client Endpoint	
	Function	Parameters	Function	Parameters
Channel Open	socket	RAX: Socket Handle	socket	RAX: Socket Handle
Channel Open	bind	RCX: Socket Handle	connect	RCX: Socket Handle
		RDX: Server Address & Port		RDX: Server Address & Port
Channel Open	accept	RAX: New Socket Handle		
		RCX: Socket Handle		
		RDX: Client Address & Port		
Send	send	RCX: New Socket Handle	send	RCX: Socket Handle
		RDX: Buffer Address		RDX: Buffer Address
Receive	recv	RCX: New Socket Handle	recv	RCX: Socket Handle
		RDX: Buffer Address		RDX: Buffer Address
Channel Close	closesocket	RCX: New Socket Handle	closesocket	RCX: Socket Handle

The communication channel is set up by both of the endpoints. The function *socket* should be called to create their own socket on both endpoints. After the sockets are created, the server endpoint binds the socket to its service address and port by calling the function *bind*. Then the server endpoint calls the function *accept* to accept the client connection. The client will call the function *connect* to connect to the server. When the function *accept* return successfully, a new socket handle will be generated and returned for further data transfer between the server endpoint and the connected client endpoint. After all these operations are performed successfully, the channel is established and the data transfer can start. During the channel open stage, server endpoint has two socket handles, the first one is used to listen to the connection from the client, while the second one is created for real data transfer. Figure4.3 shows the channel open process for TCP and UDP.

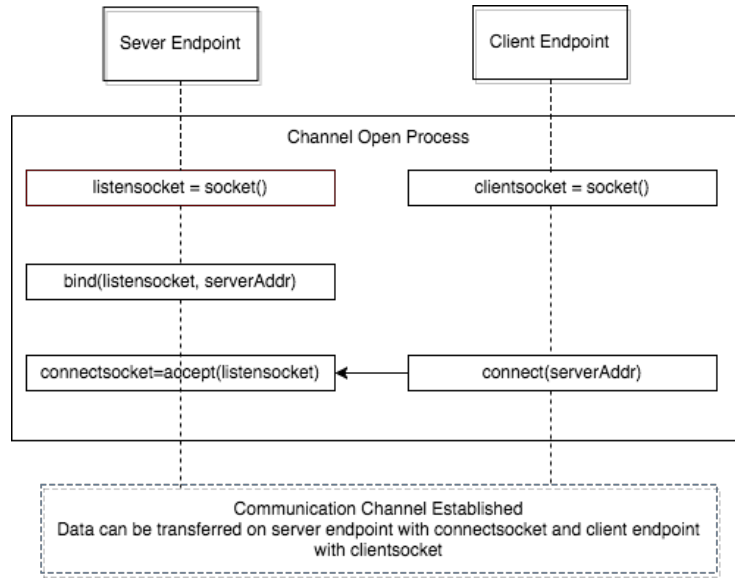

Figure 4.3: Channel Open Model for TCP and UDP

4.3 Event Locating Algorithm: *eventfilter* ()

The concerned events in a communication are channel open, channel close, send and receive events. These events are identified as system function calls in this work. A function call in the trace starts from the function call instruction to the function return instruction. The input parameters' value and input buffer content should be retrieved from the memory state of the the function call instruction line while the return value, output parameters' value and output buffer content should be retrieved from the memory state of the function return instruction line. Tables in section 4.2 indicate all the functions of the communication methods as well as the concerned parameters. Following the windows calling convention, the concerned parameter value or buffer address can be found in the corresponding register or stack positions. The buffer content can be found in the memory address in the reconstructed memory state. Each event can be completed by different function calls. For example, for the client endpoint in TCP communication method, both *socket* and *connect* function call are considered to be the channel open events. The functions list for a communication method is needed as a input of this algorithm. Tables in Section 4.2 give the examples of function list of the events for some communication methods. The algorithm presented in this section is designed for locating all function calls provided in the function list as events of one communications method. If more than one communication methods are being investigated, this algorithm should be run multiple times, each for a method. Events in the output event list is sorted by time of occurrence.

Since the function list usually contain a very small number of functions compared to the instruction line number in the execution trace, the time complexity of this algorithm is $O(N+M)$, N and M are the instruction line numbers of the two traces in the duel-trace.

Algorithm 2: Event Locating Algorithm

Input: *trace, funcset*

Output: *event_trace*

```

1 event_trace  $\leftarrow$  List(Event);
2 while not at end of trace do
3   for  $f \in \text{funcset}$  do
4     if Is function call of  $f$  then
5       event.funN =  $f.funN$  event.startline  $\leftarrow$  current Line number;
6       event.endline  $\leftarrow$  find function return instruction line;
7       event.inputs  $\leftarrow$  reconstruct memory of event.startline from the trace and
          get input values of  $f.pars$ ;
8       event.outputs  $\leftarrow$  reconstruct memory of event.endline from the trace and get
          outputs values of  $f.pars$ ;
9       event.type  $\leftarrow$   $f.type$ ;
10      success  $\leftarrow$  get the success code from event.outputs;
11      if success then
12        event_trace.add(event);
13 return event_trace;
```

4.4 Stream Identification Algorithm: *streamfilter* ()

The events located in the *event_trace* may correspond to different *stream*, the next step in the communication identification algorithm is to identify them for each *stream*. The input of this algorithm the *event_trace* from the “Event Locating Algorithm”. Since the input *event_trace* is sorted by time of occurrence and the channel open events should always happen before other events, it is reasonable to assume the new stream can be identified by its first channel open function call. The identification for TCP and UDP server endpoints are slightly complicated than the other ones, due to its own channel open mechanism. The output of this algorithm is the *stream_trace*. Each stream in this *stream_trace* consist of the sub streams. The concepts of the stream and sub streams are defined in SectionA.

Algorithm 3: Stream Identification Algorithm

Input: *event_trace*

Output: *stream_trace*

```

1 stream_trace  $\leftarrow$  Map(String, List(EndPoint));
2 for event  $\in$  event_trace do
3   if event is a channel open event then
4     handle  $\leftarrow$  get the handle identifier from the function parameter list;
5     stream  $\leftarrow$  stream_trace.get (handle);
6     if event is an accept (event) function call for TCP or UDP then
7       newHandle  $\leftarrow$  get the second socket handle identifier which is the return
          value from the function parameter list;
8       stream_trace.remove (handle);
9       stream_trace.add (newHandle, endpoint);
10    if endpoint is null then
11      stream = New Stream ();
12      stream_trace.add (hanele, endpoint);
13    stream.openStream.add (event);
14    if event is a channel send event then
15      handle  $\leftarrow$  get the handle from the function parameter list;
16      stream  $\leftarrow$  stream_trace.get (handle);
17      if stream is not null and stream.complete is False then
18        stream.sendStream.add (event);
19    if event is a channel receive event then
20      handle  $\leftarrow$  get the handle from the function parameter list;
21      stream  $\leftarrow$  stream_trace.get (handle);
22      if stream is not null and stream.complete is False then
23        stream.receiveStream.add (event);
24    if event is a channel close event then
25      handle  $\leftarrow$  get the handle from the function parameter list;
26      stream  $\leftarrow$  stream_trace.get (handle);
27      if stream is not null then
28        stream.closeStream.add (event);
29        stream  $\leftarrow$  True;
30 return stream_trace;

```

4.5 Stream Matching Algorithm: *streammatch()*

The communication identification algorithm aims at identifying all the communication of a concerned communication method from the dual-trace. The input of this algorithm is the two *stream_trace* from the dual-trace. The output of this algorithm is the communication list. Each communication recognized from the dual_trace contains two *streams*. The channel of a communication defined in Section 3.2 is not explicitly represented in the output but it was implicitly used in this algorithm.

In the communication identification algorithm, it first try to match two *streams* to a channel only by their identifiers. In this level, the matching depends on channel open mechanisms which are different from communication method to communication method. For TCP and UDP the matching can be considered as local address and port of server endpoint matching with remote address and port of client endpoint. For Named Pipe, it uses the file name, while for Message Queue, it uses the queue name as the identifier for matching of two endpoints.

The first level matching can not guarantee the exact endpoints matching and channel identification. There are two situations which false negative error might emerge. Take Named Pipe for example, the first situation is multiple (more than two) interacting programs shared the same file or queue as their own channel. Even though the channels are distinct for each communication, but the file or queue used is the same one. For example, the Named Pipe server is connected by two clients using the same file. In the server trace, there are two *streams* found. In each client trace, there is one *stream* found. For the dual_trace of server and client1, there will be two possible identified communications, one is the real communication for server and client1 while the other is the false negative error actually is for server and client2. The *stream* in client1's trace will be matched by two *streams* in the server's trace. The second situation is the same channel is reused by the different endpoints in the same programs. For example, the Named Pipe server and client finished the first communication and then closed the channel. After a while they re-open the same file again for another communication. Since the first level matching is only base on the identifiers and the first and the second communications have the same identifier since they used the same file. Similar situations can also happen in Message Queue, TCP and UDP communication methods.

To reduce the false negative error, the second level matching should be applied, which is also being named as transmitted data verification algorithm. On top of the endpoint identifiers matching, further data verification should be applied to make sure the matching is reliable. This verification crossly compare the sent and received data in both *streams* in the first level matching. If the transmitted data in the *streams* are considered to be identical, the matching is confirmed, otherwise it was a false negative error. However, we still can not exclude all the false negative errors, due to the data transmitted in two communication can be identical. Figure 4.4 indicates the

ineffective second level matching scenario and the effective one.

Figure 4.4: Second Level Matching Scenarios

The following subsections discuss the algorithms for these two level matching. In Section 4.2, I elaborate the channel open process and the data transfer categories for the concerned communication methods. Based on the different channel opening process, two algorithms are developed for the communication identification, one is for Named Pipe and Message Queue, the other is for TCP and UDP. The inputs of these two algorithms are the same, two *stream.traces* from the original dual_trace.

The data transfer characteristics divided the communication methods into reliable and unreliable transmissions. Named Pipe and TCP fall in the reliable category while Message Queue and UDP fall in the unreliable one. The second level matching algorithms are different for these two categories. The corresponding second level data verification algorithms are being used in the communication identification algorithms. The inputs of the transmitted data verification algorithms are *streams* matched in the first level matching while the output a boolean to indicate if the transmitted data of these two *streams* are matched and the verified data.

4.5.1 Stream Matching Algorithm for Named Pipe and Message Queue

For Named Pipe and Message Queue, only one channel open function is being called in each *stream*. So in the below algorithm, when it try to get the channel open event from the *stream.openStream* list, only one event should be found and return. The channel identifier parameters can be found in the *event.inputs* of the channel open event. The identifier for Named Pipe is the file name of the pipe while for Message Queue is the format queue name of the queue. This algorithm finds out all the possible communications regardless some of them might be false negative errors.

Algorithm 4: Stream Matching Algorithm for Named Pipe and Message Queue

Input: *stream_trace₀*, *stream_trace₁*

Output: *cos* = {*co_y* : 0 ≤ *y* ≤ *Y*}

```

1 cos ← Map⟨String, List⟨Communication⟩⟩;
2 for stream0 ∈ stream_trace0 do
3   openEvent0 ← get the opening event from stream0.openStream;
4   channelId0 ← get the channel identifier from openEvent0.inputs;
5   for stream1 ∈ stream_trace1 do
6     openEvent1 ← get the opening event from stream1.openStream;
7     channelId1 ← get the channel identifier from openEvent1.inputs;
8     if channelId0 == channelId1 then
9       DataVerified = dataVerify(stream0, stream1, outputdata);
10      if DataVerified == True then
11        communication = New Communication();
12        communication.stream0 = stream0;
13        communication.stream1 = stream1;
14        communication.dataMatch = outputdata;
15        cos.add(communication);
16 return cos;

```

4.5.2 Stream Matching Algorithm for TCP and UDP

For TCP and UDP multiple functions are collaborating to create the final communication channel. The local address and port of the server endpoint and the remote address and port of the client endpoint are used to identify the channel. This algorithm first try to retrieve the local address and port of the server endpoint and remote address and port from client endpoint. Then it try to match

two endpoints by comparing the local and remote address and port. Transmitted data verification also applied in this algorithm.

Algorithm 5: Stream Matching Algorithm for TCP and UDP

Input: $stream_trace_0, stream_trace_1$

Output: $cos = \{co_y : 0 \leq y \leq Y\}$

```

1   $cos \leftarrow Map\langle String, List\langle Communication \rangle \rangle;$ 
2  for  $stream0 \in stream\_trace_0$  do
3       $socketEvent0 \leftarrow \text{get the socket} () \text{ event from } stream0.openStream;$ 
4       $bindEvent0 \leftarrow \text{get the bind} () \text{ event from } stream0.openStream;$ 
5       $connectEvent0 \leftarrow \text{get the connect} () \text{ event from } stream0.openStream;$ 
6      for  $stream1 \in stream\_trace_1$  do
7           $socketEvent1 \leftarrow \text{get the socket} () \text{ event from } stream1.openStream;$ 
8           $bindEvent1 \leftarrow \text{get the bind} () \text{ event from } stream1.openStream;$ 
9           $connectEvent1 \leftarrow \text{get the connect} () \text{ event from } stream1.openStream;$ 
10         if  $socketEvent0! = null \text{ AND } socketEvent1! = null$  then
11             if  $bindEvent0! = null \text{ AND } connectEvent1 == null$  then
12                  $localServerAddr \leftarrow \text{get serverAddr from } bindEvent1.inputs;$ 
13             else if  $bindEvent1 == null \text{ AND } connectEvent0! = null$  then
14                  $remoteServerAddr \leftarrow \text{get serverAddr from } connectEvent1.inputs;$ 
15             else
16                 Break the inner For loop;
17             if  $localServerAddr == remoteServerAddr$  then
18                  $DataVerified = dataVerify(stream0, stream1, outputdata).$ 
19                  $communication = New\ Communication();$ 
20                  $communication.stream0 = stream0;$ 
21                  $communication.stream1 = stream1;$ 
22                  $communication.dataMatch = outputdata; cos.add(communiction);$ 
22 return  $cos;$ 

```

4.5.3 Data Verification $dataVerify()$ for Named Pipe and TCP

As described in Section 3.1.1, the data being received by one endpoint should always equal to or at least is sub string of the data being sent from the other endpoint in a communication for the

reliable transmission methods, such as Named Pipe and TCP. So the data verification algorithm is in data union level. The send data union is retrieved by the concatenation of the input buffer content of the send events in the send stream of an endpoint. The receive data union is retrieved by the concatenation of the output buffer content of the receive events in the receive stream of the other endpoint. The input of this algorithm is the two *streams* from two traces which are being matched in the first level.

Algorithm 6: Transmitted Verification by Data Union

Input: *stream0, stream1*

Output: send data union and receive data union of two streams

```

1 return Indicator of if transmitted data union are considered to be identical
2 send1  $\leftarrow$  empty string;
3 send2  $\leftarrow$  empty string;
4 recv1  $\leftarrow$  empty string;
5 recv2  $\leftarrow$  empty string;
6 for sendEvent  $\in$  stream0.sendStream do
7   sendmessage  $\leftarrow$  get the input buffer content from the sendEvent.inputs;
8   send0.append(sendmessage);
9 for sendEvent  $\in$  stream1.sendStream do
10  sendmessage  $\leftarrow$  get the input buffer content from the sendEvent.inputs;
11  send1.append(sendmessage);
12 for recvEvent  $\in$  stream0.receiveStream do
13  recvmessage  $\leftarrow$  get the output buffer content from the recvEvent.outputs;
14  recv0.append(recvmessage);
15 for recvEvent  $\in$  stream1.receiveStream do
16  recvmessage  $\leftarrow$  get the output buffer content from the recvEvent.outputs;
17  recv1.append(recvmessage);
18 if recv0 is substring of send1 AND recv1 is substring of send0 then
19   return True;
20 else
21   return False;

```

4.5.4 Data Verification *dataVerify()* for MSMQ and UDP

For the unreliable communication methods, the data packets being transmitted are not delivery and ordering guaranteed. So it is impossible to verify the transmitted data as a whole chunk. Fortunately, the packets arrived to the receivers are always as the original one from the sender. Therefore, we perform the transmitted data verification by single events instead of the whole stream. This algorithm basically goes through *events* of the *sendstream* in one *stream* trying to find the matched receive event in the *receivestream* in the other *stream*. And then calculate the fail packet arrival rate. The fail packet arrival rate should be comparable to the packet lost rate. So we set the packet lost rate as the threshold to determine if the transmitted data can considered to be identical in both directions. The packet lost rate can be various from network to network or even from time to time for the same network. The inputs of this algorithm are the copies of two *streams* from two traces which are being matched and the packet lost rate as the threshold. I use copies instead of original data is to modify the input list directly in the algorithm. The threshold should be an integer. For example if the lost rate is 5%, the threshold should be set as 5.

Algorithm 7: Transmitted Verification by Data of Events

Input: *stream0, stream1*

Output: matched event list of two endpoints

```

1 return Indicator of if transmitted data union are considered to be identical
2 sendPktNum0  $\leftarrow$  stream0.sendStream.length;
3 sendPktNum1  $\leftarrow$  stream1.sendStream.length;
4 recvPktNum0  $\leftarrow$  0;
5 recvPktNum1  $\leftarrow$  0;
6 eventMatches  $\leftarrow$  List(EventMatch);
7 for sendEvent  $\in$  stream0.sendStream do
8   sendmessage  $\leftarrow$  get the input buffer content from the sendEvent.inputs;
9   for recvEvent  $\in$  stream1.receiveStream do
10    recvmessage  $\leftarrow$  get the output buffer content from the recvEvent.outputs;
11    if sendmessage == recvmessage then
12      recvPktNum0 ++;
13      stream1.receiveStream.remove(recvEvent);
14      eventMatch = NeweventMatch();
15      eventMatches.add(eventMatch);
16 if (sendPktNum0 - recvPktNum0) * 100 / sendPktNum0 > threshold then
17   return False;
18 for sendEvent  $\in$  stream1.sendStream do
19   sendmessage  $\leftarrow$  get the input buffer content from the sendEvent.inputs;
20   for recvEvent  $\in$  stream0.receiveStream do
21    recvmessage  $\leftarrow$  get the output buffer content from the recvEvent.outputs;
22    if sendmessage == recvmessage then
23      recvPktNum1 ++;
24      stream0.receiveStream.remove(recvEvent);
25 if (sendPktNum1 - recvPktNum1) * 100 / sendPktNum1 > threshold then
26   return False;
27 return True;

```

4.6 Data Structures for Identified Communications

In the previous sections, I elaborate all the essential algorithms to identify the communications. The information of identified communications should be organized properly for the further presentation or visualization to the user. In this section, I define the output data structures to fulfil this requirement. There are totally two major data set. The first one is clustered as communications aligning the definition at Section 3.2. The second one is clustered by endpoints in the traces. The reason to provide the second data set is due to the false negative errors of the channel identification. The identified endpoint lists of the traces provide more original data information. So with other assistant information and the access of this relatively original information of the dual-trace, the user has more flexibility to analysis the dual-trace. The data structures have been used in the algorithms implicitly.

Algorithm 8: Data Structure for Identified Communications

```

1 communications  $\leftarrow$  Map(String, List(Communication));
   stream_traces  $\leftarrow$  Map(String, List(Stream)); struct {
2   Stream stream0           // stream0 is from trace0 of the dual-trace
3   Stream stream1           // stream1 is from trace1 of the dual-trace
4   DataMatch dataMatch
5 } Communication
6 union {
7   DataUnionMatch unionMatch // For data union verification
8   List  $\langle$  EventMatch  $\rangle$  eventMatches // For data event verification
9 } DataMatch
10 struct {
11   String sData1           // send data union of endpoint1
12   String rData1 // receive data union of endpoint1, substring of sData2
13   String sData2           // send data union of endpoint2
14   String rData2 // receive data union of endpoint2, substring of sData1
15 } DataUnionMatch
16 struct {
17   Event event1           // event1 is from endpoint1
18   Event event2           // event2 is from endpoint2
19 } EventMatch
20 struct {
21   Int handle
22   List  $\langle$  Event  $\rangle$  openStream
23   List  $\langle$  Event  $\rangle$  closeStream
24   List  $\langle$  Event  $\rangle$  sendStream
25   List  $\langle$  Event  $\rangle$  receiveStream
26 } Stream
27 struct {

29   Int endlene
30   Map  $\langle$  String, String  $\rangle$  inputs
31   Map  $\langle$  String, String  $\rangle$  outputs
32 } Event

```

Chapter 5

Feature Prototype On Atlantis

In this section, I describe the design of the feature prototype of communication identification from the dual_trace. This feature is implemented on Atlantis and is built on top of Atlantis' other features, such as "memory reconstruction", "function inspect" and "views synchronization". Atlantis is an assembly trace analysis environment. It provides many powerful and novel features to assist assembly level execution trace analysis.[5] This prototype implemented the algorithms described in Chapter4 as well as the user interfaces for the feature.

This prototype consist of four main components: 1) user defined setting for defining the concerned communication methods' function set. 2) a view that can parallely present both traces in the dual_trace. 3) two identification features: Stream identification and communication identification. 4) functionality that allow user to access the identification result.

5.1 User Defined Function Set

As emphasized in Section4.2, the function set for each communication method can be different depends on the implementation solution of the method. Furthermore, there are so many communication methods in the real world and not all of them are being analyzed by the user. Instead of using hard coded function sets, a configuration file in Json format is used for the users to define their concerned communication methods and the corresponding function set. This function sets will be the input for the communication identification. All concerned communication methods have its own function set. The identification features implemented in this prototype iterate all methods in the Json configuration file named "communicationMethods.json" and identify all communications of each method. This configuration includes the communication method, their function set for the communication events and the essential parameters of each function. A default template is given

for user reference, this default template is generated by Atlantis when it was launched and stored in the .tmp folder in the trace analysis project folder. The default template example can be find in SectionC.

5.2 Parallel Editor View For Dual_Trace

The dual_trace consist of two execution traces which are interacting with each other. Presenting them in the same view makes the analysis for the user much easier. The strategy to open parallel editor view is that open one trace as the normal one and the other as the dual_trace of the current opened one. A new menu option in the project navigation view are created to open the second trace as the dual_trace of the current active trace. The implementation of the parallel editor take the advantage of the existing SWT of Eclipse plug-in development. The detail of the implementation can be found in SectionD. Figure5.1 shows this menu option and FigureD shows the parallel editor view.

Figure 5.1: Menu Item for opening Dual_trace

Figure 5.2: Parallel Editor View

5.3 Identification Features

I implemented two identification features, one is stream identification for both traces in the dual_trace, the other is the communication identification. These two features align to the “stream identification algorithm” and “communication identification algorithm” designed in Chapter4. The implementation of these two identification features relies on the existing “function inspect” feature of Atlantis. The called functions’ name can be inspected by search of the symbolic name in the executable binary or any DLLs which used by the program at the time when it is traced. By importing the DLLs and executable binary, Atlantis can recognize the function call from the execution trace by the function names. Therefore the corresponding DLLs or executable binaries for both traces in the dual_trace have to be loaded into Atlantis before conducting the identification.

A new menu “Dual_trace Tool” with three menu options is designed for these two identification features. In this menu, two options are for conducting the identification which are “Stream Identification” and “Communication Identification” while one is for loading the DLLs and executable binary which is “Load Library Exports”. Currently, the “Load library export” function can only

load libraries for the trace in the active editor. So this item in the menu has to be run twice separately for each trace of the dual_trace. Figure 5.3 shows this new menu in Atlantis. When the user perform any of the identification features, there is the prompt dialog as shown in Figure 5.4 which asks the user what communication methods they want to identify from the dual_trace. This list is provided by the configuration file I mention in Section 5.1. The user can select one or multiple methods.

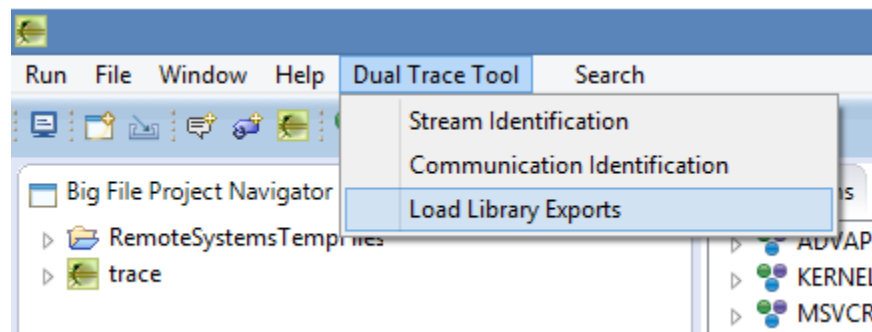

Figure 5.3: Dual_trace Tool Menu

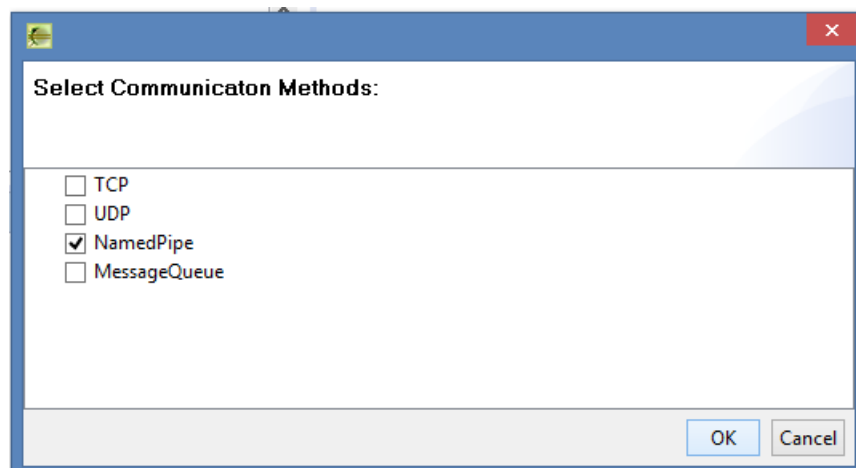

Figure 5.4: Prompt Dialog for Communication Selection

A new view named “Communication” is designed for presenting the result of the identification of streams and communications. Since the user can have multiple selection for communication methods they concern, the output identification result contains all the identified communications or streams of all the concerned communication methods and the identified results are clustered by methods. There are two sub tables in this view, the left one is for the stream identification result while the right one is for communication identification result. The reason for putting this two result

in the same view is for easy access and comparison of the data for the users. Figure 5.6 shows this view with result data in it. Each time when the user rerun the identification features the result in the corresponding table will be refreshed to show only the latest identification result. But the other table will not be affected. For example, if the user run the “Stream Identification” feature first, the stream identification result will show on the left table of the view. And then the user run the “communication Identification”, the communication identification result will be shown on the right table while the left one still holding the last stream identification result.

Figure 5.5: Communication View for Showing Identification Result

5.4 Identification Result View and Result Navigation

Atlantis is a analysis environment that has various views to allow user access to different information from the trace, such as the memory and register state of the current instruction line. Moreover, these views synchronize automatically with the editor view. These functionality and information also benefit the communication analysis of the dual_trace. Providing the user a way to navigate from the identified result to the traces in the editors allows them to take advantage of the current existing functionality of Atlantis and make their analysis of the dual_trace more efficient.

In the result list, each event entry is corresponding to a function call. The functions were called at function call line and all the inputs of the function calls can be recovered from the memory state of this instruction line. The functions returned at the return instruction lines, all the outputs of the function calls can be recovered in the memory state of the the return instruction line. From the event entries, this implementation provide two different ways for the user to navigate back to where the function begins and ends. When the user “double click” on an entry, it will bring the user to the start line of the function in the corresponding trace editor. When the the right click on the event entry, a prompted menu with the option “Go To Line of Function End” will show up as in Figure???. Clicking on this option will bring the user to the return line of this function in the trace editor. All other views update immediately with this navigation.

Figure 5.6: Right Click Menu on Event Entry

Moreover, the “remove” option as shown in Figure5.7 in the right click menu on the “stream” or “communication” entries is provided for the user to remove the selected “stream” or “communication” entry. This provides the user the flexibility to get rid of the data that they don’t care.

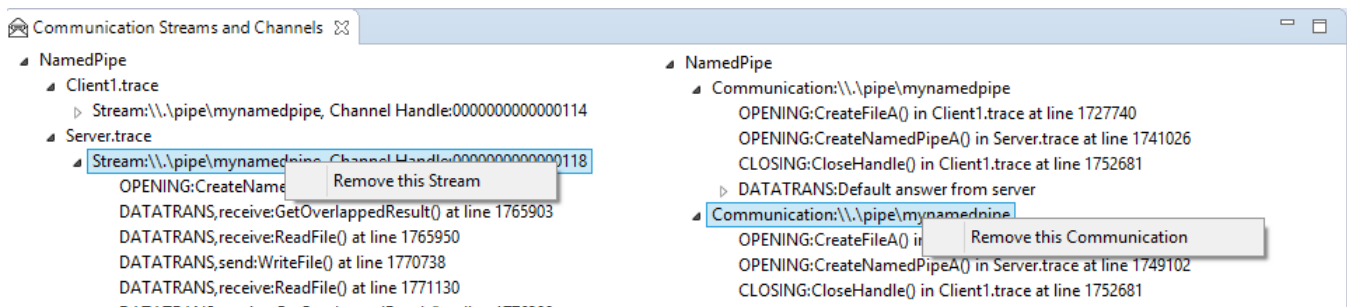

Figure 5.7: Right Click Menu on Event Entry

Chapter 6

Evaluation

This evaluation aimed to experimentally evaluate the model for communication analysis and the identification algorithms. It focus on evaluating the model and and algorithms. By the evaluation, it should be able to know if the captured dual_traces contain sufficient information of the communication model in ChapterChapter3. The evaluation also verify the design of the algorithms, for their correctness and efficiency.

User case study is not included in this thesis and can be the future work. The feature prototype implementation is not evaluated and can be part of the user case study. But I used the implemented feature on Atlantis to conduct the evaluation experiments.

In this section, I describe the design of the evaluation. Two Evaluation experiments are conducted for this evaluation. All the programs in these two experiments were written in C++ and the source code can be found in SectionE. Our search partner DRDC provided the captured traces, the used .dll files and the source code of the programs for the experiments. Evaluation results are provided for each experiment. At the end, I discuss the result of the experiments.

6.1 Evaluation Experiments

Both of the conducted experiments are about named pipe communication method. The following two subsections provides the details of the experiments and their result.

6.1.1 Experiment 1

In the first experiment, two programs communicated with each other through a synchronous Named pipe channel. One of the programs acted as the Named pipe server while the other as the client.

Figure6.1 is the sequence diagram of the interaction between the server and client. Traces were captured while these two program were running and interacting. The two captured traces are analysis as dual_trace *exp1* in this experiment. I used the implemented features in Atlantis to analyse this dual_trace. I ran the “Stream identification” and “Communication identification” operations for this dual_trace. The identified streams, communication and the processing time are listed in Figure6.2.

Figure 6.1: Sequence Diagram of Experiment 1

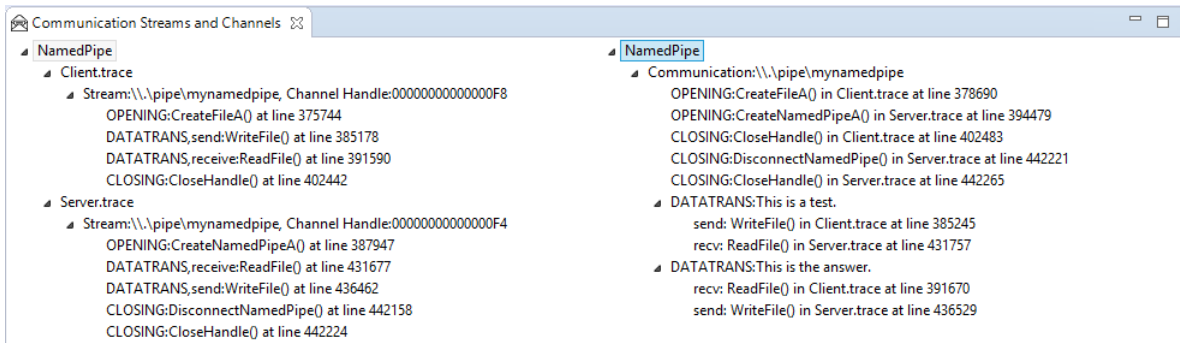

Figure 6.2: Identification result of *exp1*

6.1.2 Experiment 2

In the second experiment, one program was running as the Named pipe server. In this server program, four named pipes were created and can be connected by up to four client at a time. Two other programs as the Named pipe clients connected to this server. Those two clients (client 1 and client 2) used the identical program but run in sequence. Figure6.3 is the sequence diagram of the interaction among the server and clients. The function calls' sequence is only a possible combination from analyzing the source code. The real happening sequence can be vary from program run to program run. Traces were captured at the time when these five programs were running and interacting. One trace for each program. I only analyzed three traces which are considered as two dual_traces, *exp2.1* and *exp2.2*. *exp2.1* consist of traces of server and client 1 and *exp2.2* consist of traces of server and client 2. I also ran the "Stream identification" and "Communication identification" operations for these two dual_trace. The identified streams, communication and the processing time are listed in Figure6.4 and Figure6.5.

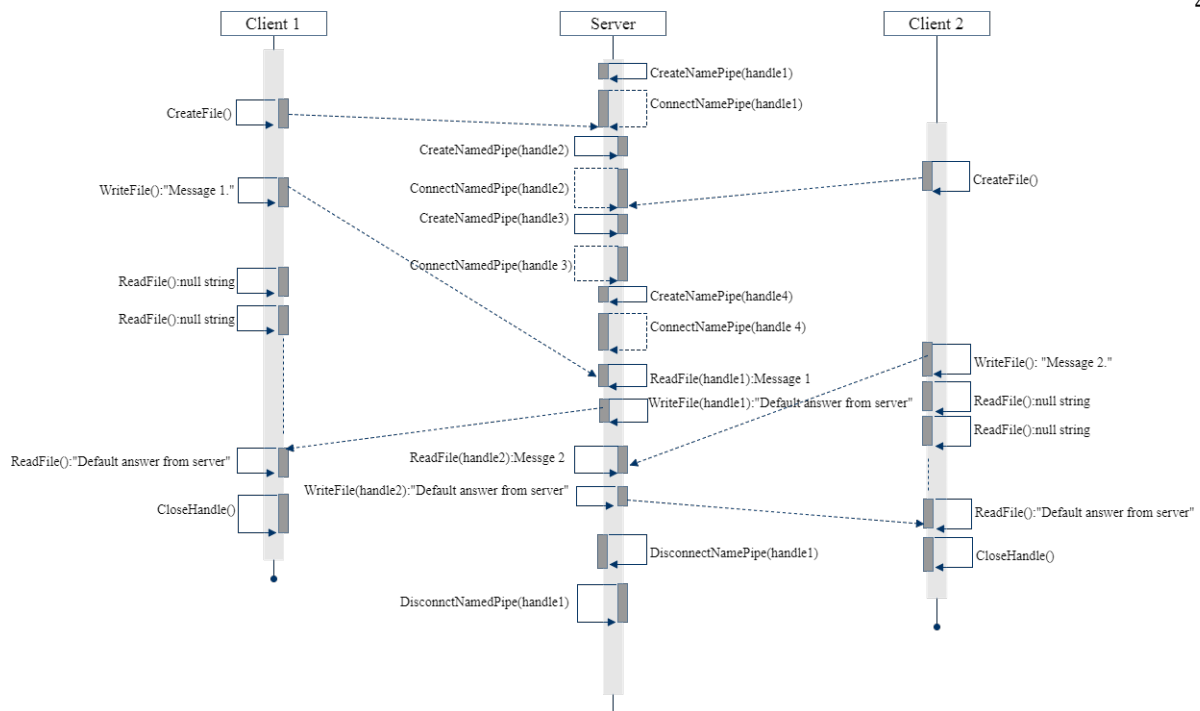

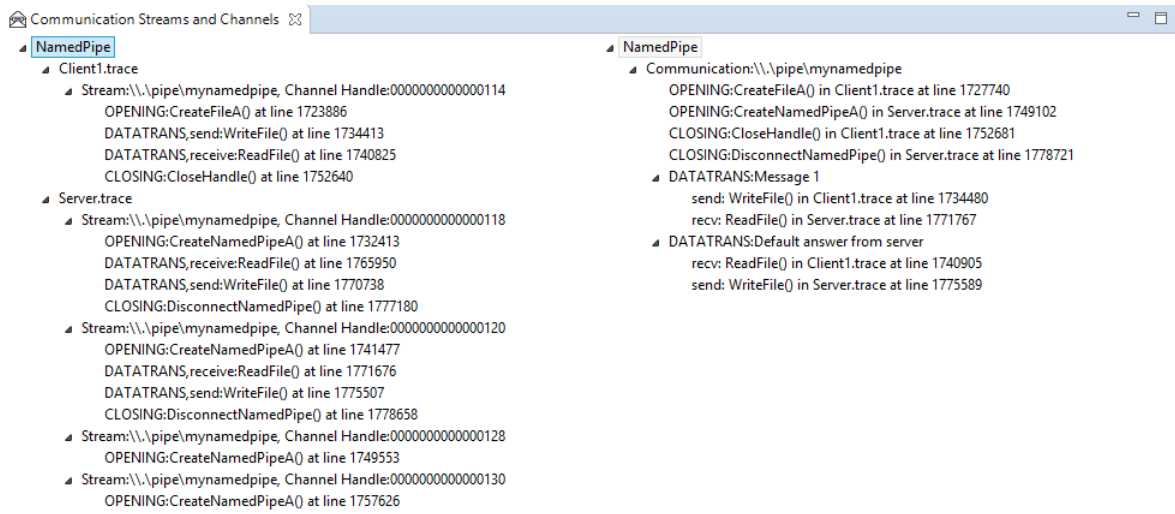

Figure 6.3: Sequence Diagram of Experiment 2

Figure 6.4: Identification result of *exp2.1*

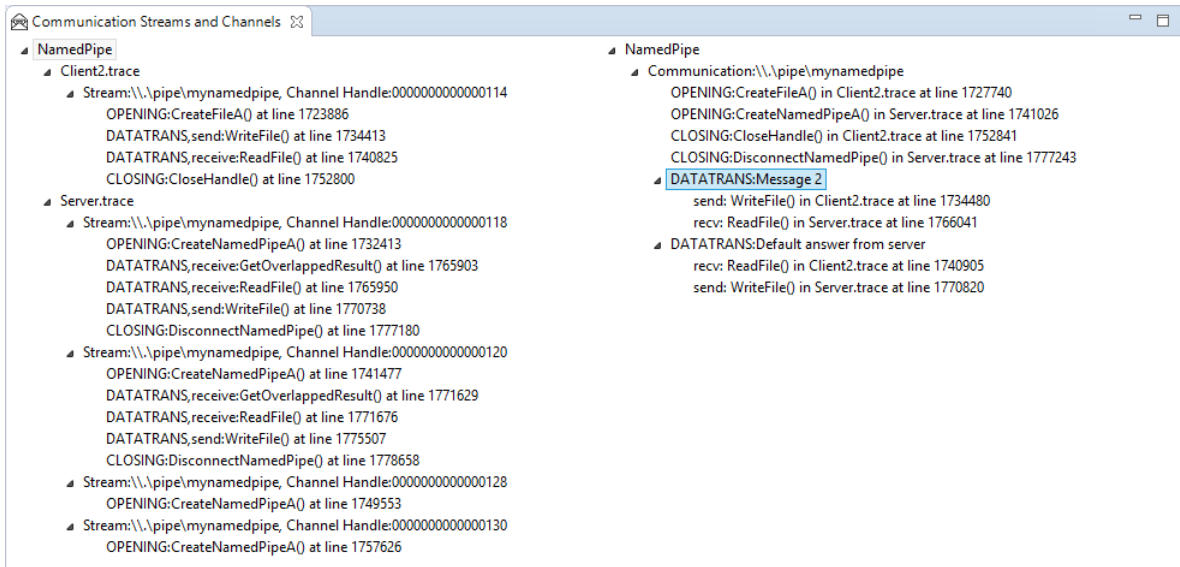

Figure 6.5: Identification result of *exp2.1*

6.2 Discussion

In the result of *exp1*, there are one stream identified in client trace and one in server trace, and these two streams are matched into a communication of this dual_trace. This identification result represents the actual communication happen between the named pipe server and client. In the result of *exp2.1* and *exp2.2*, there are one stream identified in client traces and four in server trace respectively for each dual_trace. The streams are further matched and verified and eventually one communication is identified for each dual_trace. The result aligns to the sequence diagram in Figure6.3.

Chapter 7

Conclusions and Future Work

In this thesis, I present the designed communication identification models. This model consist of three sub models, communication definition model, dual_trace model and identification matching model for matching the elements in the dual_trace to the elements in the communication definition. This model provide the guideline for communication analysis for software security engineers and researchers in assembly execution trace level. By understanding this model, it should be possible for them to conduct their own communication analysis, identifying the concerned communication methods from the captured execution traces of interacting programs.

I also developed the essential algorithms for the communication identification. The high level algorithm is generalizable for all communication methods' identification while the stream identification and matching algorithm are distinct for each communication method according to their channel open and data transfer mechanisms. However, the developed algorithms provides clear and referable examples to develop your own algorithm for communication methods which are not discussed in this thesis.

On top of the existing execution trace analysis environment Atlantis, I implemented the communication identification features. The design provides the users a way to extend their concerned communication methods through the configuration file. The extended user interface allows the users to conduct the communication and stream identification from the dual_traces and navigate back from the identified result to the views of the trace in Atlantis. This feature prototype is a novel feature for conducting multiple trace analysis for reverse engineering at the time when this thesis was written.

The experiment evaluation preliminary proves the usability of the model and the algorithms. It also demonstrate the limitation for eliminating the false negative error of the communication identification. Other information is needed to assist the identification in order to improve its accuracy.

This thesis illustrates the novel idea and approach for dynamic program analysis which considerate the interaction of two programs. This idea is valuable due to the fact that programs or malware in the real world work collaboratively. The analysis of the communication and interaction of the programs provide more reliable information for vulnerability detection and program analysis.

Future work can be divided in two directions. One is extending the model to be more generalize for all kinds of interaction but not only the message transferring communications while the other is conducting user studies of the model and feature design to get a more concrete result of their usefulness.

Appendix A

Terminology

1. **Endpoint:**An instance in a program at which a stream of data are sent or received (or both). Such as a socket handle of TCP or a file handle of the named pipe.
2. **Channel:**A conduit connected two endpoints through which data can be sent and received.
3. **Channel open event:**Operation to create and connect an endpoint to a specific channel.
4. **Channel close event:**Operation to disconnect and delete the endpoint from the channel.
5. **Send event:**Operation to send a trunk of data from one endpoint to the other through the channel.
6. **Receive event:**Operation to receive a trunk of data at one endpoint from the other through the channel.
7. **Channel open stream:**A set of all channel open events regarding to a specific endpoint.
8. **Channel close stream:**A set of all channel close events regarding to a specific endpoint.
9. **Send stream:**A set of all send events regarding to a specific endpoint.
10. **Receive stream:**A set of all receive events regarding to a specific endpoint.
11. **Stream:**A stream consist of a channel open, a channel close, a send and a receive streams of an endpoint.

Appendix B

Microsoft x64 Calling Convention for C/C++

1. RCX, RDX, R8, R9 are used for integer and pointer arguments in that order left to right.
2. XMM0, 1, 2, and 3 are used for floating point arguments.
3. Additional arguments are pushed on the stack left to right. ...
4. Parameters less than 64 bits long are not zero extended; the high bits contain garbage.
5. Integer return values (similar to x86) are returned in RAX if 64 bits or less.
6. Floating point return values are returned in XMM0.
7. Larger return values (structs) have space allocated on the stack by the caller, and RCX then contains a pointer to the return space when the callee is called. Register usage for integer parameters is then pushed one to the right. RAX returns this address to the caller.

Appendix D

Code of the Parallel Editors

Two essential pieces of code are listed for the parallel editor. One is for splitting the editor area for two editors while the other is to get the active parallel editors later on for dual trace analysis.

D.1 The Editor Area Split Handler

Listing D.1: code in OpenDualEditorsHandler.java

```
public class OpenDualEditorsHandler extends AbstractHandler {
    EModelService ms;
    EPartService ps;
    WorkbenchPage page;

    public Object execute(ExecutionEvent event) throws ExecutionException {
        IEditorPart editorPart = HandlerUtil.getActiveEditor(event);
        if (editorPart == null) {
            Throwable throwable = new Throwable("No active editor");
            BigFileApplication.showErrorDialog("No active editor", "Please open one file
                ↪ first", throwable);
            return null;
        }

        MPart container = (MPart) editorPart.getSite().getService(MPart.class);
        MElementContainer m = container.getParent();
        if (m instanceof PartSashContainerImpl) {
            Throwable throwable = new Throwable("The active file is already opened in one
                ↪ of the parallel editors");
            BigFileApplication.showErrorDialog("The active file is already opened in one
                ↪ of the parallel editors",
                "The active file is already opened in one of the parallel editors",
                ↪ throwable);
            return null;
        }
    }
}
```

```

    }
    IFile file = getPathOfSelectedFile(event);

    IEditorDescriptor desc = PlatformUI.getWorkbench().getEditorRegistry().
        ↪ getDefaultEditor(file.getName());
    try {
        IFileUtils fileUtil = RegistryUtils.getFileUtils();
        File f = BfvFileUtils.convertFileIFile(file);
        f = fileUtil.convertFileToBlankFile(f);
        IFile convertedFile = ResourcesPlugin.getWorkspace().getRoot().
            ↪ getFileForLocation(Path.fromOSString(f.getAbsolutePath()));
        convertedFile.getProject().refreshLocal(IResource.DEPTH_INFINITE, null);
        if (!convertedFile.exists()) {
            createEmptyFile(convertedFile);
        }

        IEditorPart containerEditor = HandlerUtil.getActiveEditorChecked(event);
        IWorkbenchWindow window = HandlerUtil.getActiveWorkbenchWindowChecked(event);
        ms = window.getService(EModelService.class);
        ps = window.getService(EPartService.class);
        page = (WorkbenchPage) window.getActivePage();
        IEditorPart editorToInsert = page.openEditor(new FileEditorInput(convertedFile)
            ↪ , desc.getId());
        splitEditor(0.5f, 3, editorToInsert, containerEditor, new FileEditorInput(
            ↪ convertedFile));
        window.getShell().layout(true, true);

    } catch (CoreException e) {
        e.printStackTrace();
    }

    return null;
}

private void createEmptyFile(IFile file) {
    byte[] emptyBytes = "".getBytes();
    InputStream source = new ByteArrayInputStream(emptyBytes);
    try {
        createParentFolders(file);
        if (!file.exists()) {
            file.create(source, false, null);
        }
    } catch (CoreException e) {
        e.printStackTrace();
    } finally {
        try {
            source.close();
        } catch (IOException e) {
            // Don't care
        }
    }
}

```

```

    }

    private void splitEditor(float ratio, int where, IEditorPart editorToInsert, IEditorPart
        ↪ containerEditor,
        FileEditorInput newEditorInput) {
        MPart container = (MPart) containerEditor.getSite().getService(MPart.class);
        if (container == null) {
            return;
        }

        MPart toInsert = (MPart) editorToInsert.getSite().getService(MPart.class);
        if (toInsert == null) {
            return;
        }

        MPartStack stackContainer = getStackFor(container);
        MElementContainer<MUIElement> parent = container.getParent();
