ACKNOWLEDGEMENTS

I would like to thank:

my cat, Star Trek, and the weather, for supporting me in the low moments.

Supervisor Main, for mentoring, support, encouragement, and patience.

Grant Organization Name, for funding me with a Scholarship.

I believe I know the only cure, which is to make one's centre of life inside of one's self, not selfishly or excludingly, but with a kind of unassailable serenity-to decorate one's inner house so richly that one is content there, glad to welcome any one who wants to come and stay, but happy all the same in the hours when one is inevitably alone.

Edith Wharton

DEDICATION

Just hoping this is useful!

Chapter 1

Introduction

Many network application vulnerabilities occur not just in one application, but in how they interact with other systems. These kinds of vulnerabilities can be difficult to analyze. Dual-trace analysis is one approach that helps the security engineers to detect the vulnerabilities in the interactive software. A dual-trace consist of two execution traces that are generated from two interacting applications. Each of these traces contains information including CPU instructions, register and memory changes of the running application. Communication information of the interacting applications is captured as the register or memory changes on their respective traced sides.

This work is focusing on helping reverse engineers for interacting software vulnerabilities detection. We first investigated and modeled four types of commonly used channels in Windows communication foundation in order to help the reverse engineers to understand the APIs, the scenarios and the assembly trace related perspectives of these channels. Then we built a tool prototype for the communication event locating and visualization of dual-traces. Finally, we design an experiment to test our prototype and evaluate its practicality.

add an section to summarize the conclusion later

The Methodology used for this work composed of 7 major steps. To make this work executable, 1)I defined the problem by understanding the requirement from our research partner DRDC. 2) I obtained the related background knowledge by literature review. Then 3) I model the abstract communication channels. Based on these channel models,4) I develop algorithms to synchronize the communication events happen in the channel. After that, 5) I match the real channels used in Windows Communication Foundation to my channel models, verify their consistency with my models. Finally 6)I implement the synchronization algorithms for the dual-trace analysis and verify them by the dual-traces from DRDC.

1.1 Define the Problem

A dual-trace consists of two execution traces that are generated from two interacting applications. The trace analysis is based only on the assembly level execution trace which contain the instructions and memory change of a running application. Beside all the factors in single trace analysis, dual-trace analysis has to analyze the communications of the applications in the traces. A communication between two applications including the communication channel open, all data exchanging events, the communication channel close. Correspondingly, a full communication definition in the dual-trace should consist of the channel opening events in both sides, data sending and receiving events, and the the channel closing events in both sides. Each of these events consist of function call and related data from the memory record. In some cases there might be some events lacking from the trace, such as no data exchange after a channel is open, or the traces end before the channel was closed. However, the channel open is critical, without that there is no way to locate all other events in the traces. The goal communication analysis of dual-trace is to rebuild all the user concerned communication channels from the dual-trace.

1.2 Obtain Background Knowledge

I did a some background reading in the reverse engineering filed, focusing more on the vulnerabilities detection domain to better understand the current state and needs. In addition, to locate the communication event of the dual-trace, I need to investigate the communication methods' APIs to understand their structure in the assembly level traces. I need to know how the functions for channel setup and the functions for messages sending/receiving work. The system functions I was looking for is in C++ level. I have to know the C++ function names, related parameters, return value and so on. Furthermore, to understand their structure in the assembly level trace, I have to know the calling conventions in assembly, such registers/memory for parameters or return value.

1.3 Model the Communication Channels

There are two abstract models for communication based on the communication behavior. One is the order guaranteed communication model and the other is order in-guaranteed communication model. I define how the communication happens as well as all the data send/receive scenario in each model. Later on the real communication channels will be categorized into these two models.

1.4 Develop the Dual Trace Synchronization Algorithms

1.5 Apply the Channel Models to Windows APIs

I investigate 4 types of communication channels in Windows Communication Foundation and match each of them to the developed channel model. These 4 types are Only Named pipe, MQMS, HTTP, and TCP/UDP socket. The matching includes two steps: 1. Put each type of communication channel in the modeling categories by verify the existence of the message send/receive scenario. 2. Define the function callings for each event types in the channel, such as channel opening and closing, data sending and receiving.

1.6 Implement the Trace Synchronization Algorithms

1.7 Evaluate the Communication Channel Rebuilt Feature in Atlantis

Chapter 2

Background

This section introduces several background knowledge or information that related to this work. First I describe what is software security and how important it is as well as our previous approach to assist detection of software vulnerabilities by assembly level trace analysis. Second, I introduce the general assembly level trace as well as some tracer to generate it. Third, I discuss how software interaction affect the behavior of the software and how they related to the software vulnerabilities. Then I talk about Windows Communication Foundation in which the communication channels type used are targeted by this work. Finally, we mention some important Windows function calling conventions without which you can not picture what the function calls look like in the assembly level.

2.1 Software Security

The internet grows incredibly fast in the past few year. More and more computers are connected to it in order to get service or provide service. The internet as a powerful platform for people to share resource, meanwhile, introduces the risk to computers in the way that it enable the exploit of the vulnerabilities of the software running on it. Accordingly, the emphasize placed on computer security particularly in the field of software vulnerabilities detection increases dramatically. It's important for software developers to build secure applications. Unfortunetely, this is usually very expensive and time consuming and somehow impossible. On the other hand, finding issues in the built applications is more important and practical. However this is a complex process and require deep technical understanding in the perspetive of reverse engineering.[2].

2.2 Software Vulnerability Detection

A common approach to detect existing vulnerabilities is fuzzing testing, which record the execution trace while supplying the program with input data up to the crash and perform the analysis of the trace to find the root cause of the crash and decide if that is a vulnerability[1]. Execution trace can be captured in different levels, for example object level and function level. But my research only focus on those that captured in instruction and memory reference level. There are two main reasons for analysis system-level traces. First, it is for analysis of the software provided by vendor whose source code are not available. The second one is that low level trace are more accurately reflect the instructions that are executed by multicore hardware[7].

2.3 Assembly Level Trace

There are many tools that can trace a running program in assembly instruction level. IDA pro [3] is a widely used tool in reverse engineering which can capture and analysis system level execution trace. Giving open plugin APIs, IDA pro allows plugin such as Codemap [5] to provide more sufficient features for "run-trace" visualization. PIN[4] as a tool for instrumentation of programs, provides a rich API which allows users to implement their own tool for instruction trace and memory reference trace. Other tools like Dynamic ?? and

2.4 Software Interaction

Applications nowaday do not alway work isolately, many software appear as reticula collaborating systems connecting different modules in the network[?] which make the discovery of vulnerabilities even harder. The communication and interaction between modules affect the behaviour of the software. Without regarding to the synergy information, analysis of the isolated execution trace on a single computer is usually futile.

2.5 Atlantis

Applications nowaday do not alway work isolately, many software appear as reticula collaborating systems connecting different modules in the network[?] which make the discovery of vulnerabilities even harder. The communication and interaction between modules affect the behaviour of the

software. Without regarding to the synergy information, analysis of the isolated execution trace on a single computer is usually futile.

2.6 Windows Communication Foundation

We limited our research only on the communication types used in Windows Communication Foundation(WCF) for now. Windows Communication Foundation (WCF) is a framework for building service-oriented applications. Using WCF, developers can send data as asynchronous or asynchronous messages from one service endpoint to another. We are not going deep into the details of this framework but only mention the most common communication methods it supports in its messaging layer. The messaging layer in WCF is composed of channels. A channel is a component that processes a message in some protocol. There are two types of channels in WCF: transport channels and protocol channels. In this work we only care about transport channels. Transport channels read and write messages from the network. Examples of transports are named pipes, MSMQ, TCP/UDP or HTTP, all of which are involved in the scope of this work.

2.7 Assembly Calling Convention

Before we jumping into a specific communication channel, it is important to know some basic assembly calling convention. Calling Convention is different for operating system and the programming language. Since we are looking into the messaging methods being used in windows communication framework, and since our case study is running on a Microsoft* x64 system, we only list the Microsoft* x64 calling convention for interfacing with C/C++ style functions:

- 1. RCX, RDX, R8, R9 are used for integer and pointer arguments in that order left to right.
- 2. XMM0, 1, 2, and 3 are used for floating point arguments.
- 3. Additional arguments are pushed on the stack left to right. ...
- 4. Parameters less than 64 bits long are not zero extended; the high bits contain garbage.
- 5. Integer return values (similar to x86) are returned in RAX if 64 bits or less.
- 6. Floating point return values are returned in XMM0.

7. Larger return values (structs) have space allocated on the stack by the caller, and RCX then contains a pointer to the return space when the callee is called. Register usage for integer parameters is then pushed one to the right. RAX returns this address to the caller.

Chapter 3

Modeling

The modeling aims to model the communication between two software in the perspective of dual-trace analysis. It focuses on describing what information about the communication would be captured and how that information organized in the dual-trace. The model did not cover all communication methods in the real world, but gives a general structure of the communication in the dual-trace as well as the analysis pattern of the communication. Some communication methods are leveraged in this model to give a more concrete view of the model and guideline for further investigation of other communication methods which are not covered in this work.

In this section, I define the communications between two software. Meanwhile, I list and categorize the communication methods which will be the instances of this model. After that, I present the communication model for the dual-traces analysis. This model includes two levels. The first level is the model of the general stages for all communication methods. They are 1. channel opening stage, 2. data transfer stage and 3. channel close stage. The second level models give the idea of how to investigate the patterns of the communication stages defined in the first level by modeling the stages for the selected communication methods. The modeling idea and concepts can be reused for those ones not covered in this work. Only channel open stage and data transfer stage are explored since the channel close stage is very straightforward.

This model is the guideline of what information of communication can and should be retrieved from the dual-trace for interacting software, and how they would be reconstructed and presented to the users. The second level models are also essential for the design of the communication channel identification algorithms and communication event synchronization algorithms.

3.1 Communication of Two Applications

The communication defined in this work is data transfer activities between two running software through a specific channel. Some collaborative activities between the software such Remote procedure call is out of the scope of this research. Communication among multiple software(more than two) is not discussed in this work.

In general, these data sharing communications can be divided into two main categories: interprocess communication and network communication. There are various communication methods in both of these two categories. Table 3.1 lists those ones investigated by this research.

Table 3.1: Communication Methods Discussed in This Work

	Inter-Process	Network
Methods	Named Pipes	TCP
Methous	Message Queue	UDP

3.2 First Level Communication Model: General Model

The general model describes how a full communication happens and is generalizable for all communication. After the illustration of the model, I instantiate this model to some communication methods in Windows APIs. Windows API functions called to consist a full communication on each endpoint are listed separately for communication methods. These function call lists are the concerned information from the dual-trace in the analysis.

3.2.1 Modelling

Before describing the model, I would like to define the terms which are being used in the model Terms:

endpoint:

A software or application at which data are sent or received (or both).

channel:

A conduit connected two endpoints through which data can be sent and received

send:

One or more function calls to send a truck of data from one endpoint to the other through the channel.

receive:

One or more function calls to receive a truck of data at one endpoint from the other through the channel.

The general communication model defines a full communication. It consists of three stages and two endpoints which transferring data to each other. These three stages are 1. channel opening stage, 2. data transfer stage and 3. channel close stage. Both of these two communicating endpoints open or connect to the communication channel before they start the data transfer and close or disconnect from the channel after finishing the data transfer. The data transfer should happen in between of the channel open and the channel close.

Figure 3.1 illustrates the general communication model indicating how communications happen between two endpoints. In the channel open stage, each endpoint needs to call one or multiple channel open/connection functions, depending on the types of the channel endpoints(server or client endpoint), different functions might be called. In the data transfer stage, data is being sent into the channel in one endpoint and received in the other endpoint. Both endpoints can be senders and receivers throughout the communication. Same as channel open stage, in the channel close stage, one or multiple functions might be called by both endpoints to ensure a proper resource release and disconnection from the channel.

The channel can be reopened again to start new communications after the close stage. However, the reopened channel will be treated as a new communication cycle with its own stages. From the trace analysis point of view, function calls of all stages in the communications are not mandatory being captured or happen. However channel open stage is necessary for the identification of a channel.

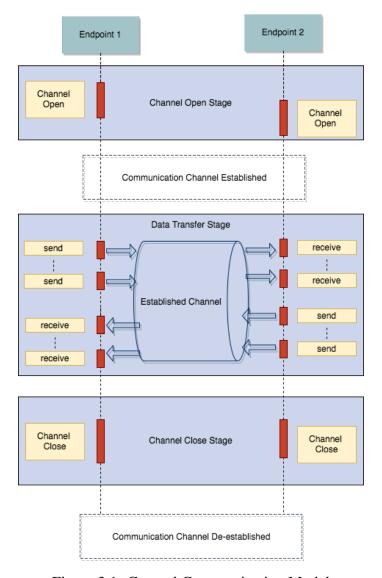

Figure 3.1: General Communication Model

3.2.2 Model Instantiation

I reviewed the Windows APIs of some communication methods. Windows API is very sophisticated and multiple solutions are provided by windows to fulfill similar communication methods. Windows application developers can choose what API set they want to use in their solutions. Its impossible to enumerate all the communication methods and all API combinations for each communication method. I only leveraged some communication methods.

For each communication method, a function list is provided for reference. However, this function list should not be considered as the only combination or solution for each communication

method. With the understanding of the model, it should be fairly easy to draw out lists for other communication methods or other API set for the same communication methods. Moreover, the instances of this model only demonstrate Windows C++ APIs. This model may be generalizable to other operating systems with the effort of understanding the APIs of those operating system.

In the following subsections, Windows APIs with function names, essential parameters and registers which holding those parameters are listed for the four investigated communication methods. These functions APIs are those ones supported in most Windows operating systems, such as Windows 8, Window 7. The registers for the parameters are concluded according to the Windows calling convention and can change over time.

These lists can be examples and references for the users of the implementation when they need to generate their own communication methods setting. The user can use their own concerned API list for the dual-trace analysis of different communication methods by putting the function lists in JSON format as the setting. More detail of the communication methods setting will be discussed in Section 5, when I discuss the implementation of communication analysis of the dual-trace.

Named Pipes

A named pipe is a communication method for the pipe server and one or more pipe clients. The pipe has a name, can be one-way or duplex. Both the server and client can read or write into the pipe.[?] In here we only consider one server versus one client communication. One server to multiple clients scenario can always be divided into multiple server/client communications thanks to the characteristic that each client/server communication has a separate conduit. The server and client are endpoints in the model. We call the server "server endpoint" while the client "client endpoint". The server endpoint and client endpoint of a named pipe share the same pipe name, but each endpoint has its own buffers and handles.

A named pipe server is responsible for the creation of the pipe, while clients can connect to the pipe after it created. The creation and connection of a named pipe will return the handle ID of that pipe. As we mentioned before, each client or server endpoint has its own handles, so the returned handle Ids of the pipe creation function of the server and pipe connection function from each client are different. These handler Ids will be used later when data are being sent or received to specify a pipe.

There are two modes for data transfer in the named pipe communication method, synchronous and asynchronous. Modes affect the functions used to complete the send and receive operation as well as the operation of the functions. I list the related functions for both synchronous mode and asynchronous mode. The create channel functions for both modes are the same but with different

input parameters. The functions for send and receive message are also the same for both cases. However, the operation of the send and receive functions are different for the different mode. In addition, an extra function *GetOverlappedResult* is being called to check if the sending or receiving operation finish, the output message will be stored in the overlap structure whose memory address saved in the function's output parameter Overlap Structure Address. Table3.2 lists the necessary functions for synchronous mode while Table3.3 lists the necessary functions for the asynchronous mode for a full communication.

Table 3.2: Function APIs for Synchronous Named Pipe

Message Queue

Message Queuing (MSMQ) is a communication method to allow applications which are running at different times across heterogeneous networks and systems that may be temporarily offline can still communicate with each other. Messages are sent to and read from queues by applications. Multiple sending applications can send messages to and multiple receiving applications can read messages from one queue. [6] The applications are the endpoints of the communication. In this work, only one sending application versus one receiving application case is considered. Multiple senders to multiples receiver scenario can always be divided into multiple sender/receiver. Both endpoints of a communication can send to and receive from the channel.

The endpoints of the communication can create the queue or use the existing one. However, both of them have to open the queue before they access it. The handle ID returned by the open queue function will be used later on when messages are being sent or received to identify the queue.

Similar to Named Pipe, Message Queue also has two modes, synchronous and asynchronous. Moreover, the asynchronous mode further divides into two operations, one with callback function while the other without. If with the callback function, the callback function would be called when the send or receive operations finish. If without callback function, the general function *MQGe-tOverlappedResult* should be called by the endpoint to check if the message sending or receiving

operation finish, the output message will be stored in the overlap structure whose memory address saved in the function's output parameter Overlap Structure Address. Table 3.4 lists the necessary functions for synchronous mode while Table 3.5 and Table 3.6 list the necessary functions for the asynchronous mode with and without callback for a full communication.

Table 3.4: Function APIs for Synchronous MSMQ

TCP and UDP

TCP and UDP are the most fundamental transport methods in computer networking. TCP is a reliable transport method while UDP is not. In Windows programming, these two methods shared the same set of APIs regardless the input parameter and operation behavior is different. In Windows socket solution, one of the two endpoints is the server while the other one is the client. The server opens its socket and listens to the connection from clients. The client connects to the server after opening its own socket.

Table 3.7 lists the necessary functions consist a UDP or TCP full communication. For the channel opening, the function *socket* should be called on both endpoints. The sever endpoint call the function *bind* to bind to its local service address and port. Then the server endpoint calls the function *accept* to accept the connection from the clients. The client will call the function *connect* to connect to the server. When the function *accept* return successfully, a new socket handle will return for further data transfer. During the channel open stage, server endpoint has two socket handles, the first one is used to listen to the connection from the client, while the second one is created for real data transfer.

Table 3.7: Function APIs for TCP and UDP

Stage	Server Endpoint		Client Endpoint	
Stage	Function	Parameters	Function	Parameters
	socket	RAX: Socket Handle	socket	RAX: Socket Handle

3.3 Second Level Communication Model: Channel Open Model for Individual Communication Method

This section exemplifies the channel open model for the individual communication methods. This model describes how the channels are set up for communication of different method. Based on the opening process, two channel open models are depicted, one for Named pipe and Message Queue, the other for TCP and UDP. The channel identification algorithms developed in Section 4 are based on these two models.

3.3.1 Model for Named Pipe and Message Queue

In this model, the channel is already existed or created by one endpoint before the other can connect to it. So that the channel opening process is only two endpoints connect to the channel. The channel creation can happen at the same time with the channel open, but it will be treat the same as the existed channel in this model. Figure 3.2 shows the channel set up model for Named Pipe and Message Queue.

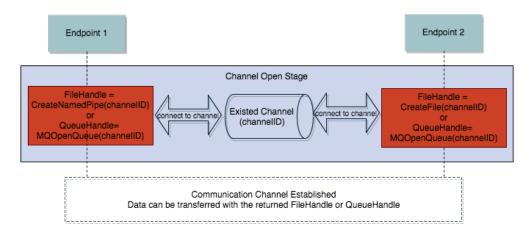

Figure 3.2: Channel Open Model for for Named Pipes and Message Queue

3.3.2 Model TCP and UDP

In this model, the channel is set up by both of the endpoints. Each endpoint has to create its own socket. After the sockets are created, the server endpoint binds the socket to it service address and port. The client endpoint connects to the service. Server endpoint accepts the client connection and generates a new data transfer socket for data transfer with this connected client. After all these operations are performed successfully, the channel is established and the data transfer can start. Figure 3.3 shows the channel set up the model for TCP and UDP.

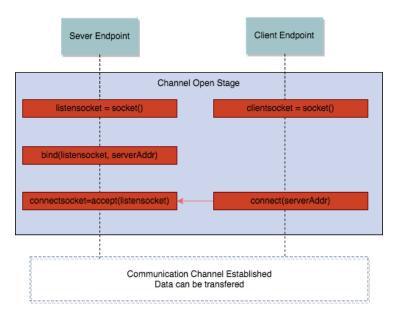

Figure 3.3: Channel Open Model for TCP and UDP

3.4 Second Level Communication Model: Data Transfer Model for Individual Communication Method

The four communication methods in this work all have its own properties in the perspective of data transfer. In this section, I summarize the elemental characteristics of each communication method. Furthermore, data transfer models for each communication method were designed respectively regarding to their characteristics. The data transfer scenarios are covered in the models. The models in this section are fundamental for the design for communication event synchronization algorithms. The detail of these algorithms will be discussed in Section 4.

3.4.1 Named Pipe

The basic data transfer characteristics of Named Pipe are:

- Bytes received in order
- Bytes sent as a whole trunk can be received in segments
- Only the last trunk can be lost

Based on these characteristics, the data transfer model of it can be summarized in Figure 3.4.

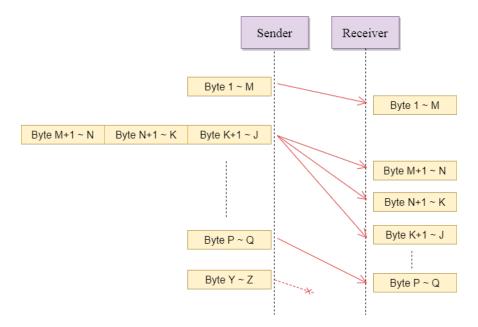

Figure 3.4: Data Transfer Model for Named Pipe

3.4.2 Message Queue

The basic data transfer characteristics of Message Queue are:

- Bytes sent in packet and received in packet, no bytes reorganized
- Packets can lost
- Packets received in order

Based on these characteristics, the data transfer model of it can be summarized in Figure 3.5.

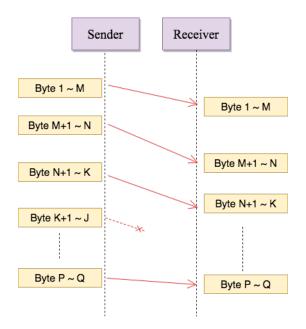

Figure 3.5: Data Transfer Model for Message Queue

3.4.3 TCP

The basic data transfer characteristics of TCP are:

- Bytes received in order
- No data lost
- Sender window size is different from receiver's window size, so packets can be re-segmented

Based on these characteristics, the data transfer model of it can be summarized in Figure 3.6.

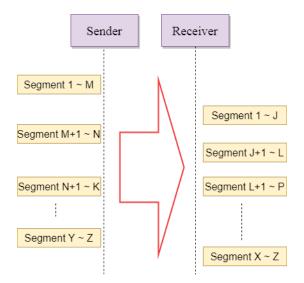

Figure 3.6: Data Transfer Model for TCP

3.4.4 UDP

The basic data transfer characteristics of UDP are:

- Bytes sent in packet and received in packet, no re-segmentation
- Packets can lost
- Packets can arrive receiver out of order

Based on these characteristics, the data transfer model of it can be summarized in Figure 3.7.

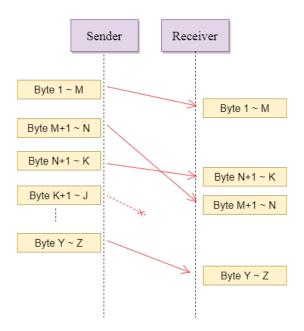

Figure 3.7: Data Transfer Model for UDP

Chapter 4

Channel Information Retrieval Algorithms

Each communication type will have its own algorithm. The algorithms take the dual-traces as input. The dual trace consists of two traces from two application communicated with each other through different communication channels. All algorithms output a list of channel, including the identifiers of the channel, the function calls in each communication stage in the general model and all send and receive function calls. In the following subsections, algorithms are listed for each communication types.

4.1 Channel Information Retrieval Algorithm for TCP

From the data transfer model of TCP channel, we can see that the sent packages can be shuffled in the receiver side. So it's meaningless to do a one-to-one send/receive matching from both ends of the channel. This algorithm search thought out the dual-trace, by matching the local and remote ip/port in the create, bind and connect function calls of the socket, identifies all channels of the dual-trace. For each channel, the send and receive function calls are catch. This algorithm will output all the recognized TCP channels. The output data structure of the TCP channel is list in Algorithm1, while the algorithm is list in Algorithm2, Algorithm3 and Algorithm4.

Algorithm 1: Output Data Structure for TCP Channel

```
struct {
   SocketSR trace1
   SocketSR trace2
} Channel
struct \ \{
   Socket
                     socket
   List( Function)
                     sends
   List( Function)
                     receives
} SocketSR
struct \ \{
   Int
              handle
   String
              local
   String
              remote
   Function
              create
   Function
              bind
   Function
              connect
   Function close
} Socket
struct \ \{
   Int
              lineNum
} Function
```

Algorithm 2: TCP Channel Information Retrival Algorithm

Input: Trace1 and Trace2 from both sides of dual-trace

Output: All TCP channels

 $channels \leftarrow List\langle Channel \rangle$

 $trace1sockets \leftarrow searchSockets (trace1)$

 $trace2sockets \leftarrow searchSockets (trace2)$

for $s1 \in trace1sockets$ do

for $s2 \in trace2sockets$ do

```
if s1.local = s2.remote AND s2.local = s1.remote then
```

 $channel.trace1.socket \leftarrow s1$

 $channel.trace2.socket \ \leftarrow s2$

channels.add (channel)

findAllSendAndRecv (trace1, channels, True)

findAllSendAndRecv (trace2, channels, Flase)

Algorithm 3: searchSockets() Function for TCP Channel Information Retrival Algorithm

```
Function searchSockets (trace):
    sockets \leftarrow Map\langle Int, Socket \rangle
    while not at end of trace do
        if socket create function call then
            socket.handle \leftarrow return value of the function call
            socket.create.lineNum \leftarrow currentline
            sockets.add(handle, socket)
        else if socket bind function call then
            handle \leftarrow \text{handle parameter of the function call}
            sockets[handle].local \leftarrow address and port parameter of the function call
            sockets[handle].bind \leftarrow \texttt{currentline}
        else if socket connect function call then
            handle \leftarrow handle parameter of the function call
            sockets[handle].remote \leftarrow address and port parameter of the function call
            sockets[handle].connect \leftarrow currentline
        else if socket close function call then
            handle \leftarrow \text{handle parameter of the function call}
            sockets[handle].close \leftarrow \texttt{currentline}
   for s \in sockets do
        if s.local = null \ \textit{OR} \ s.remote = null \ \textbf{then}
            sockets.delete(s)
    return sockets.tolist()
```

Algorithm 4: findAllSendAndRecv() Function for TCP Channel Information Retrival Algorithm

```
Function findAllSendAndRecv (trace, channels, isTrace1):
   while not at end of trace do
       if socket send function call then
          handle \leftarrow handle parameter of the function call
          sr \leftarrow getSocketSR (handle, channels, isTrace1)
          if sr! = null \ AND \ sr.socket.create.lineNum < currentline \ AND
            sr.socket.bind.lineNum < currentline AND
            sr.socket.connect.lineNum < currentline AND
            sr.socket.close.lineNum > currentline then
              send.lineNum \leftarrow currentline
              sr.sends.add(send)
       if socket receive function call then
          handle \leftarrow \text{handle parameter of the function call}
          sr \leftarrow qetSocketSR (handle, isTrace1)
          if sr! = null AND sr.socket.create.lineNum < currentline AND
            sr.socket.bind.lineNum < currentlineAND
            sr.socket.connect.lineNum < currentline AND
            sr.socket.close.lineNum > currentline then
              receive.lineNum \leftarrow currentline
              sr.receives.add(send)
Function getSocketSR (handle, channels, isTrace1):
   for c \in channels do
       if isTrace1 then
          sr \leftarrow channels.trace1
       else
          sr \leftarrow channels.trace2
       if sr.socket.handle = handle then
          return sr
```

4.2 Channel Information Retrieval Algorithm for UDP

The main difference between the UDP and TCP data transfer model is that, a UDP packet sent in the sender side always arrives as the same packet receiver side. However, the packet sent can loss and out of order. So it's meaningful to do a one-to-one send/receive matching from both ends of the channel. This algorithm applies the same search mechanism for channels as TCP, which is list in 3. However, for each channel, the catch send and receive function calls need to be matched. This algorithm will output all the recognized UDP channels. Each channel contains all matching send/receive function call pairs. The output data structure of the UDP channel is list in Algorithm5, while the algorithm is list in Algorithm6 and Algorithm7.

Algorithm 5: Output Data Structure for UDP Channel

```
struct {
   Socket trace1
   Socket trace2
   List (SRPair) trace1Totrace2
   List \( SRPair \) trace2Totrace1
} Channel
struct \ \{
   Int
              handle
   String
              local
   String
              remote
   Function create
   Function bind
   Function connect
   Function close
} Socket
struct {
   Function send
   Function recv
} SRPair
struct \ \{
   Int
              lineNum
   String
               bytes
   Socket
                  socket
} Function
```

Algorithm 6: UDP Channel Information Retrival Algorithm

```
Input: Trace1 and Trace2 from both sides of dual-trace
Output: All UDP channels
channels \leftarrow List\langle Channel \rangle
trace1sockets \leftarrow searchSockets(trace1)
trace2sockets \leftarrow searchSockets (trace2)
for s1 \in trace1sockets do
    for s2 \in trace2sockets do
       if s1.local = s2.remote AND s2.local = s1.remote then
           channel.trace1Socket \leftarrow s1
           channel.trace2Socket \leftarrow s2
           channels.add(channel)
findAllSendAndRecv (trace1, trace2, channels)
Function findAllSendAndRecv (trace1, trace2, channels):
    trace1Sends, trace2Sends, trace1Receives, trace2Receives \leftarrow List\langle Function \rangle
    while not at end of trace1 do
       if socket send function call then
          addToList(trace2Sends, False)
       if socket receive function call then
           addToList(trace2Receives, False)
    while not at end of trace2 do
       if socket send function call then
           addToList(trace2Sends, False)
       if socket receive function call then
           addToList(trace2Receives, False)
   for s \in trace1Sends do
       for r \in trace2Receives do
           if s.bytes = r.bytes then
               SRPair.send \leftarrow s
               SRPair.recv \leftarrow r
   for s \in trace2Sends do
       for r \in trace1Receives do
           if s.socket.local = r.socket.remote AND r.socket.local = s.socket.remote
            AND \ s.bytes = r.bytes \ \mathbf{then}
               SRPair.send \leftarrow s
              SRPair.recv \leftarrow r
```

Algorithm 7: Other Functions for UDP Channel Information Retrival Algorithm

```
Function addToList (List, isTrance1):
   handle \leftarrow \text{handle parameter of the function call}
   sr \leftarrow getSocketSR (handle, isTrace1)
   if \ sr! = null \ AND \ sr. socket. create. line Num < current line \ AND
     sr.socket.bind.lineNum < currentline AND
     sr.socket.connect.lineNum < currentline AND
     sr.socket.close.lineNum > currentline then
       func.lineNum \leftarrow currentline
       func.bytes \leftarrow \text{data that received when the function return}
       func.socket \leftarrow sr
       list.add(func)
Function getSocketSR (handle, channels, isTrace1):
   for c \in channels do
       if isTrace1 then
           sr \leftarrow channels.trace1
       else
           sr \leftarrow channels.trace2
       if sr.socket.handle = handle then
           return sr
Function getChannel (channels, trace1Socket, trace2Socket):
   for c \in channels do
       if trace1Socket = c.trace1 AND trace2Socket = c.trace2 then
           return c
```

4.3 Channel Information Retrieval Algorithm for Named pipe

Similar to the data transfer model of TCP channel, the sent packages can be shuffled in the receiver side in Named pipe. So we don't do one-to-one send/receive matching for Named pipe channel as neither. The channel search is based only on the name of the Named pipe. In both ends, the name for the Name pipe is identical but have different handles. For each channel, the send and receive function calls are catch. This algorithm will output all the recognized Named pipe channels. The

output data structure of the channel is list in Algorithm8, while the algorithm is list in Algorithm9, Algorithm?? and Algorithm10.

Algorithm 8: Output Data Structure for Named pipe Channel

```
struct \ \{
   pipeSR trace1
   pipeSR trace2
} RebuiltChannel
struct {
   pipeEnd
                       end
   List( Function)
                      sends
   List( Function)
                      receives
} pipeSR
struct {
   Int
               handle
   String
               pipeName
   Function
               create
   Function
               close
} pipeEnd
struct \ \{
   Int
               lineNum
} Function
```

Algorithm 9: Named Pipe Channel Information Retrival Algorithm

```
Input: Trace1 and Trace2 from both sides of dual-trace
Output: All Named Pipe channels
channels \leftarrow List\langle Channel \rangle
trace1PipeEnds \leftarrow searchPipeEnds (trace1)
trace2PipeEnds \leftarrow searchPipeEnds (trace2)
for e1 \in trace1PipeEnds do
   for e2 \in trace2PipeEnds do
        if e1.pipeName = e2.pipeName then
           channel.trace1Socket \leftarrow e1
           channel.trace2Socket \leftarrow e2
           channels.add (channel)

       else
         endSr \leftarrow channels.trace2
       if sr.socket.handle = handle then
           return endSr
```

Chapter 5

Feature Prototype On Atlantis

In this section we discuss the design of the prototype of dual-trace analysis. The tool prototype I built was based on the general communication model I described in last section. This prototype consist of three main components: user interface for defining the communication type, algorithm of locating the communication events in the dual-trace, user interface and strategy to navigate the located events to the sender and receiver traces. We provide the background information of the design of each component as well as their detail design in each corresponding subsection.

5.0.1 User Defined Channel Type By Json

In our design, we don't specify any predefined communication type but give the user ability to do that. By the user interface implemented, the user can defined their own communication type. This give the flexibility to the user to define what they are looking for. Each communication type consist of 4 system function calls. They are channel create/open in sender and receiver sides, sender's send message function and receiver's receive message function. By indicating the channel create/open functions in both sender and receiver sides, the tool can acquire the channel's identifiers. Later on the tool can match the send and received messages within a specific channel. The send and receive functions are used to located the event happened in the traces. The messages sent and received are reconstructed from the memory state when the send and receive functions are called and returned. The detail of the match algorithm will be discuss later.

Channel Searching

The called functions' name can be inspected by search of the symbolic name in the executable binary or any DLLs which used by the program at the time when it is traced. This functionality exists in the current Atlantis. By importing the DLLs and execution executable binary, Atlantis can list all called functions for the users in the Functions view. From this list, users can chose the interested functions and generate their interested communication type. In Figure 5.1 there is an action item "Add to Communication type" in the right click menu of the function entry. Figure 5.2 shows the dialogue for entering the information for the adding function. As this figure shows, users can get the existing communication type list in the drop down menu. They can choose to add the current function to an exist communication type or they can add it to a new communication type by entering a new name. For the channel create/open function, the register holding the address of channel's name as input and the register holding the handle identification of the channel as output are required. For the send/receive function, the register holding the address of the send/receiver buffer, the register holding the length of the sending/receiving message and the register holding the channel's identification are required. As there are 4 functions for each communication type users have to repeat this add function to communication type action for 4 times to generate one communication type.

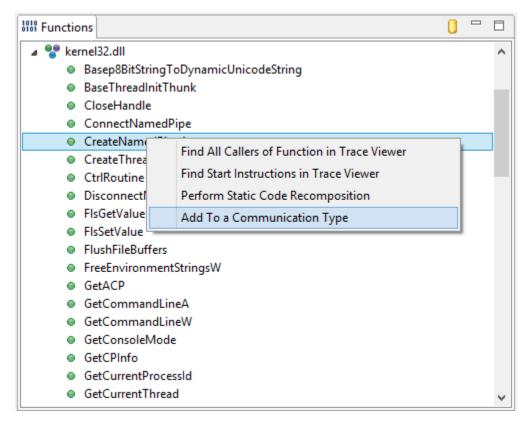

Figure 5.1: Add function to a Communication type from Functions View

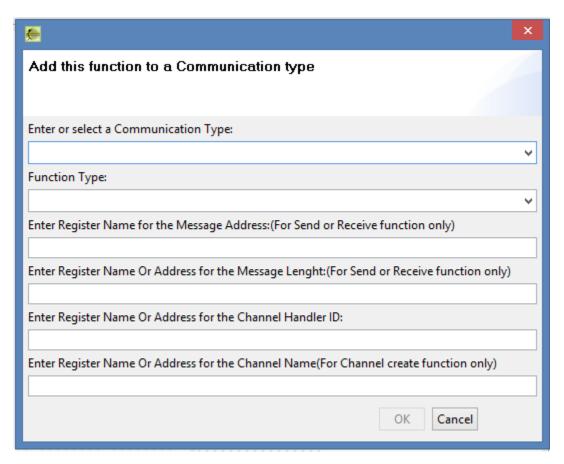

Figure 5.2: Dialog to input information for a function adding to a communication type

Communication Type Data Structure

The defined communication type will be stored in a xml file. The list below shows the data structure of one communication type.

```
<channelIdReg>RCX</channelIdReg>
            </sendFunction>
           <receiveFunction>
               <associatedFileName>Server</associatedFileName>
               <name>ReadFile </name>
               <messageAddress>RDX</messageAddress>
               <messageLengthAddress>R8</messageLengthAddress>
               <channelIdReg>RCX</channelIdReg>
            </receiveFunction>
           <sendChannelCreateFunction>
               <associatedFileName>Client </associatedFileName>
               <name>CreateFileA </name>
               <channelIdReg>RAX</channelIdReg>
               <channelNameAddress>RCX</channelNameAddress>
            </sendChannelCreateFunction>
           <receiveChannelCreateFunction>
               <associatedFileName>Server</associatedFileName>
               <name>CreateNamedPipeA </name>
               <channelIdReg>RAX</channelIdReg>
               <channelNameAddress>RCX</channelNameAddress>
            </receiveChannelCreateFunction>
        </messageType>
    </messageTypes>
</messageTypesData>
```

Communication Type View

A new view named Communication Types view is for the user defined communication types. All user defined communication type are stored in the .xml file and listed in communication type view when it's opened as shown in Figure 5.3. User can change the name of a communication type, remove an existing communication type or searching of the match message occurrences of selected communication type by selecting action item in the right click menu of an communication type entry. The matched messages are listed in the result window of the view. By clicking the entry of the search result, user can navigate to it's sender or receiver's corresponding instruction line as shown in Figure 5.4. Message content in the memory view will be shown as well.

Figure 5.3: New View: Communication Type View

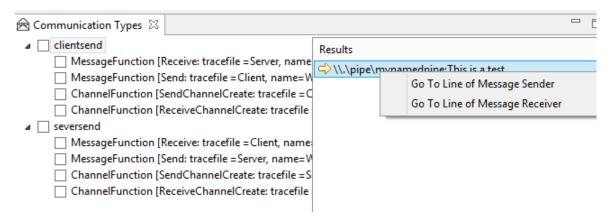

Figure 5.4: Right Click menu to navigate to send and receive event in the traces

5.0.2 Communication Event Searching

The communication event consists of the send message event in the sender side and receive message event in the receiver side. The communication event searching algorithm can be divided into three main steps: 1. search all channel create/open event in the sender and receiver side, save the handle id and corresponding channel name. 2. Search all message send and receive event in sender and receiver sides. 3. Matching the send/receive messages pair based on the channel names and message contents.

Record opened Channel

In this step the algorithm is supposed to search all the open channel both in the sender and receiver side. The found created channels are recorded in a map. The key of the map is the handler id of the channel and the value is the channel name. A channel in the sender and receiver sides will have different handler id but same channel name.

Search send and receive Message

All send message and receive message function calls will be found out in the trace. When a send function hit, the memory state of the hit instruction line will be reconstructed, and the message content can be get from the memory with the send message buffer address. When a receive function hit, the return line of that function is needed for getting the message content. The memory state of the function return line is reconstructed and the message content can be get from the reconstructed memory state with the receive message buffer address.

Matching the send/receive messages pair

After the created channel and send/receive message are found out in the sender and receiver side, a matching algorithm is used to match the send/receive message pairs.

Matching Event Data Structure

The matching event is stored in cache when the tool is running. Only the most recent search result is cached currently. If users need the previous result, they need to apply the search again. The matching Event consist of two sub-events, one is message send event while the other is message receive event. Both of these two sub-events are object of BfvFileMessageMatch. BfvFileMessageMatch is an Java class extends org.eclipse.search.internal.ui.text.FileMatch. FileMatch class containing the information needed to navigate to the trace file editor. In order to show the corresponding send/receive message in the memory view, the target memory address storing the message content is set in BfvFileMessageMatch. Two more elements: message and channel name are also set in BfvFileMessageMatch which are listed in the search result.

5.0.3 Navigation From Channel Search Result to Dual-Trace

The right click menu of an entry in the search result list has two action items: Go To Line of Message Sender and Go To Line of Message Receiver. Both of the action items allow users to

navigate to the trace Instruction view. When the user click on these items, it will navigate to the corresponding trace sender or receiver trace instruction view. Meanwhile the memory view jumps to the target address of the message buffer, and the memory state is reconstructed so that the message content in that buffer will be shown in the memory view.

Chapter 6

Evaluation

The case we used to test this prototype contains one named pipe synchronous channel between a server and a client. Client send a message to the server and server reply another message to the client.

6.0.1 Experiment Verification Design

The test cases are designed to find all the messages from client to server and all the messages from server to client. Two end to end test cases are designed for both scenarios.

In each test case, there are three test steps: 1. define the communication type by adding channel creating functions and message send/receive functions of server and client sides. 2. search for the events of the defined communication type. 3. for the occurrence of the events, navigate to the trace instruction and memory view.

Verification points are specified for each step as: 1. verify the communication types with their functions are listed in the communication view. 2. verify the message events in the dual-trace can be found and listed in the search result view. 3. verify the navigation from the result entry to the instruction view of sender trace and receiver trace.

6.0.2 Result

We used the dual-trace provided by DRDC and follow the experiment and verification design to conduct this test. Figure 6.1 shows that the user defined clientsend and serversend communication types are shown in the communication type view as well as the functions consist of the communication types. Figure 6.3 shows the search result of clientsend communication type, while Figure 6.3 shows the search result of the serversend communication type. By clicking the Go To Line of

Message Sender and Go To Line of Message Receiver action items, instruction view and memory view updated correctly. Figure 6.4 shows the server was sending out a message: This is an answer.

Chapter 7

Conclusions

7.1 Limitations

In this section, we specify the limitations of the current prototype and the reasons for them.

7.1.1 Event Status: Success or Fail

In current prototype, we only consider the success cases. For the Fail case, since the message was not successfully sent or received, there are high chance that they are not existed in the memory of the trace. From the assembly level trace, if the message was not traced in the memory, there is no way to match the sent/received message pair in the trace analysis.

7.1.2 Match Events Distinguishing

Distinguishing is considered when multiple clients connecting to the same server. Each connection is considered as an instance. In the server side all this instances have the same pipe name but different handler ID. However in the assembly trace level there is no way to match a client with it instance handler ID. In consequence, if the same content messages are being sent/received by different clients, when the user want to match the message pair between a client and the server, there is no way to distinguish the correct one from the assembly trace level. As a result, our tool will list all the matched content message event, regardless if it's from the interested client. The user can distinguish the correct ones for this client, if they have extra information.

7.1.3 Match Events Ordering

Ordering is considered when multiple messages with exactly the same content being send/receive between the client and server. If the channel is synchronous, the order of the event is always consist with the order they happen in both the sender and receive sides. However for the asynchronous channel, there are chance that the sent messages in the sender side's trace are out of order with the received messages in the received side's trace. Unfortunately, There is no way in the assembly level trace to match the exactly ones. As a result, our tool can only order the event based on the order they happen in the traces.

7.1.4 Buffer Sizes Of Sender and Receiver Mismatch

In current prototype, we only consider the success cases. For the Fail case, since the message was not successfully sent or received, there are high chance that they are not existed in the memory of the trace. From the assembly level trace, if the message was not traced in the memory, there is no way to match the sent/received message pair in the trace analysis.
